Ai and Norton (2003) state that to better understand interaction effects, one should graphically examine the interaction effects of the individual sample observations. In our context, an interaction effect is the effect that a change in *FEE* or *ANALYST* has on the partial effect of the other variable on the probability that managers will waive a misstatement that, if corrected, would cause the company to miss analysts' consensus forecast. Figure 2 illustrates the interaction effect z-statistics for each observation in the *LNAUDIT* model (Norton et al. 2004).[23] The plots show that 93 percent, 89 percent, and 90 percent of the z-statistics are negative (Table 4, Panel B) for the *ANALYST* × *LNAUDIT* interaction in Models 1a, 1b, and 1c, respectively.

---

[22] More specifically, Ai and Norton (2003, 124) illustrate that "the statistical significance of the interaction effect cannot be tested with a simple t-test on the coefficient of the interaction term β_{12}." Ai and Norton (2003) further illustrate that understanding the direction and magnitude of interactions in logit models requires more than a t-test of the coefficient on the interaction term because the interaction effect can be dependent on the other independent variables in the model. The interaction effect can thus have a direction that is opposite of the coefficient's sign. Analyzing only the marginal effect of the interaction term would be: $(\partial\varphi(u))/\partial(x_1x_2) = \beta_{12}\varphi'(u)$. Norton et al. (2004) calculate the interaction effect for each observation in the sample using the cross-partial derivative of the expected value of y as: $[(\partial^2\phi(u))/(\partial x_1\partial x_2)] = \beta_{12}\varphi'(u) + (\beta_1 + \beta_{12}x_2)(\beta_2 + \beta_{12}x_1)\varphi''(u)$.

Greene (2010) cautions against overreliance on statistical measures such as Ai and Norton's (2003) interaction effects and recommends using an alternative graphical analysis to understand the economic significance of interactions.[24] Following this advice, in Figure 3 we depict the negative *ANALYST* × *LNAUDIT* interactions, and in Panels B, D, F, and H of Table 4 we summarize the economic effects for Model 1.[25] Using the specification in Model 1a shows that the predicted probability that a waived misstatement allows companies to meet or beat analysts' consensus forecasts increases 19 percent when *ANALYST* is at its mean and *LNAUDIT* decreases one standard deviation from its mean, but increases 44 percent when *ANALYST* is one standard deviation above its mean and *LNAUDIT* decreases one standard deviation from its mean. These increases are economically significant. According to Greene (2010, 294), one can interpret an interaction effect in Figure 3 as "the change in the distance between the two sets of predicted probabilities." For example, the interaction effect in Model 1a using *LNAUDIT* is 25 percent (calculated as 44 percent − 19 percent). This interaction effect is also economically significant. Results using the specifications in Model 1b and 1c yield similar results. Figure 3 thus further confirms the presence of a negative *ANALYST* × *FEE* interaction. Taken together, the interaction effects that we document are consistent with the importance of the joint role of managers' and auditors' incentives on the waiving of qualitatively material misstatements.[26]

Turning to our last hypothesis, H4 predicts that audit committees with more financial expertise decrease the likelihood that managers will waive material misstatements. Supporting H4, we find that audit committee financial expertise is negatively related to the likelihood of managers waiving a qualitatively material misstatement in models using each of the audit fee measures and each of the model specifications across Models 1a–1c in Panels A, C, E, and G of Table 4 (*LNAUDIT*: $p = 0.03$, $p = 0.06$, and $p = 0.05$ for Models 1a, 1b, and 1c, respectively), (*ABNORMALAUDIT*: $p = 0.01$, $p = 0.02$, $p = 0.02$, respectively), (*OFFICEAUDIT*: $p = 0.06$, $p = 0.09$, $p = 0.08$, respectively), and (*FIRMAUDIT*: $p = 0.05$, $p = 0.08$, $p = 0.09$, respectively).[27] In terms of control variables, the results across Models 1a–1c in Panels A, C, E, and G of Table 4 show that forecast error is negatively

---

[23] The interaction effect z-statistics show a similar pattern when using the *ABNORMALAUDIT* and *FIRMAUDIT* variables. To avoid repetition, we report plots using the variable *LNAUDIT* as a prototypical example. Plots for the other variables are available from the authors upon request. Table 4, Panel D shows that 97 percent, 91 percent, and 94 percent of the z-statistics are negative for the *ANALYST* × *ABNORMALAUDIT* interaction in Models 1a, 1b, and 1c, respectively. Further, 99 percent, 97 percent, and 96 percent of the z-statistics are negative (Table 4, Panel H) for the *ANALYST* × *FIRMAUDIT* interaction in Models 1a, 1b, and 1c, respectively.

[24] Greene (2010, 295) "does not fault Ai and Norton's (2003) suggested calculations. Rather, we argue that the process of statistical effects about partial effects, and interaction terms in particular, produces generally uninformative and sometimes contradictory and misleading results. The mechanical reliance on statistical measures of significance obscures the economic, numerical content of the estimated model."

[25] The plots depicting the *ANALYST* × *ABNORMALAUDIT* and the *ANALYST* × *FIRMAUDIT* interaction effects show a similar pattern, and are available from the authors upon request.

[26] To examine the robustness of our results to the historical materiality approach, we re-run the analyses in Tables 4 and 5 using an indicator variable for companies using the income statement approach and an indicator variable for companies using the balance sheet approach, with the intercept being no disclosure regarding the prior approach. These variables are not significant ($p > 0.10$) in our models and do not change our inferences.

[27] We also tested whether audit committee financial expertise might mitigate managers' incentives to waive qualitatively material misstatements, i.e., the interaction of *ACEXP* × *ANALYST*. In untabled results, we find that this variable is not significant ($p > 0.10$) in our models and other results are essentially unchanged.

FIGURE 2

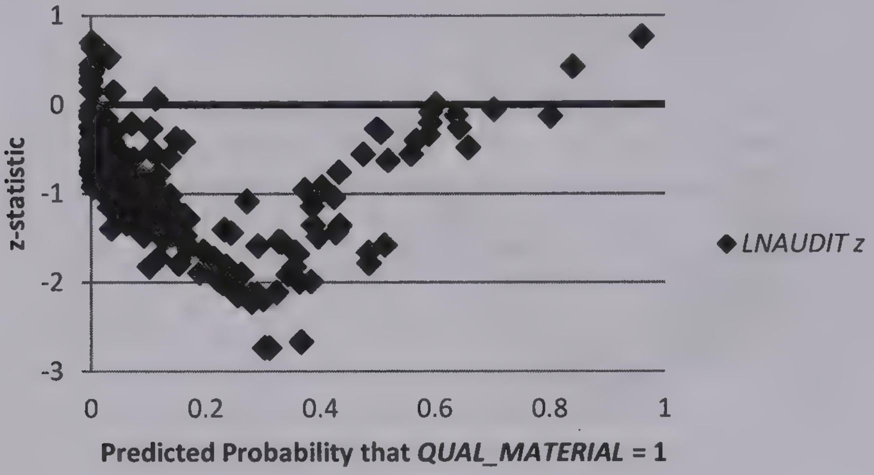
associated with *QUAL_MATERIAL*, and that the number of audit committee meetings, the presence of complex misstatements, and audit firm tenure are positively associated with *QUAL_MATERIAL*.

Models 2 and 3: Quantitative Materiality Tests (*QUANT_MATERIAL_PRETAX* and *QUANT_MATERIAL_NORM*)

We provide further tests of H2 and H4 using two measures of quantitative materiality, namely, pretax net income (Table 5, Panel A) and normal income (Table 5, Panel B). Consistent with the results that obtain using our measure of qualitative materiality, we find that audit fees are negatively related to the likelihood that auditors will allow managers to waive a quantitatively material misstatement in models using the level of audit fees (*LNAUDIT*: $p = 0.04$ and $p = 0.05$ in Panels A and B, respectively), abnormal audit fees (*ABNORMALAUDIT*: $p = 0.07$ and $p = 0.07$), and firm rank of audit fees (*FIRMAUDIT*: $p = 0.02$ and $p = 0.10$).

FIGURE 2 (continued)

Panel C: Model 1c (90 percent of z-statistics are negative)



This figure produced by the "inteff" command in Stata (Norton et al. 2004) plots observation level z-statistics for the *ANALYST* × *LNAUDIT* interaction effects by moving *ANALYST*, *LNAUDIT*, and *ANALYST* × *LNAUDIT* with all other variables at their means. The figure illustrates that Model 1a, 1b, and 1c interaction effects are predominantly negative.

The results also show that audit committee financial expertise is negatively related to the likelihood of managers waiving a quantitatively material misstatement in models using each of the audit fee measures (*LNAUDIT*: p = 0.07 and p = 0.05 in Panels A and B, respectively; *ABNORMALAUDIT*: p = 0.07 and p = 0.05; *OFFICEAUDIT*: p = 0.07 and p = 0.04; and *FIRMAUDIT*: p = 0.07 and p = 0.05). In terms of control variables, the results across Panels A–B of Table 5 show that higher levels of inventory and receivables, higher sales growth (Panel A only), and larger companies are negatively associated with *QUANT_MATERIAL*, and that the presence of complex misstatements, the presence of large blockholders, and a recent loss are positively associated with *QUANT_MATERIAL*.

Robustness Checks

Audit Firms, Audit Fees, and Client Quality

The results in Tables 4 and 5 show that our measures of audit fees are negatively related to the likelihood that managers will waive a material misstatement. We interpret this relation as indicating that auditors who receive higher audit fees protect their reputations by decreasing the extent to which they allow managers to waive material misstatements. An alternative explanation is that audit firms that charge higher fees accept higher quality clients that are less likely to have material misstatements. The extant literature generally accepts the definition of a "high-fee auditor" as a Big N auditor (Francis 2004). Given that Big N firms charge higher audit fees than non-Big N firms (Palmrose 1986), we examine this alternative explanation by re-estimating our models in Tables 4 and 5, limiting our sample to Big N client companies. We find essentially the same results in untabulated analyses, supporting our original interpretation.

FIGURE 3

(continued on next page)

Managerial Compensation

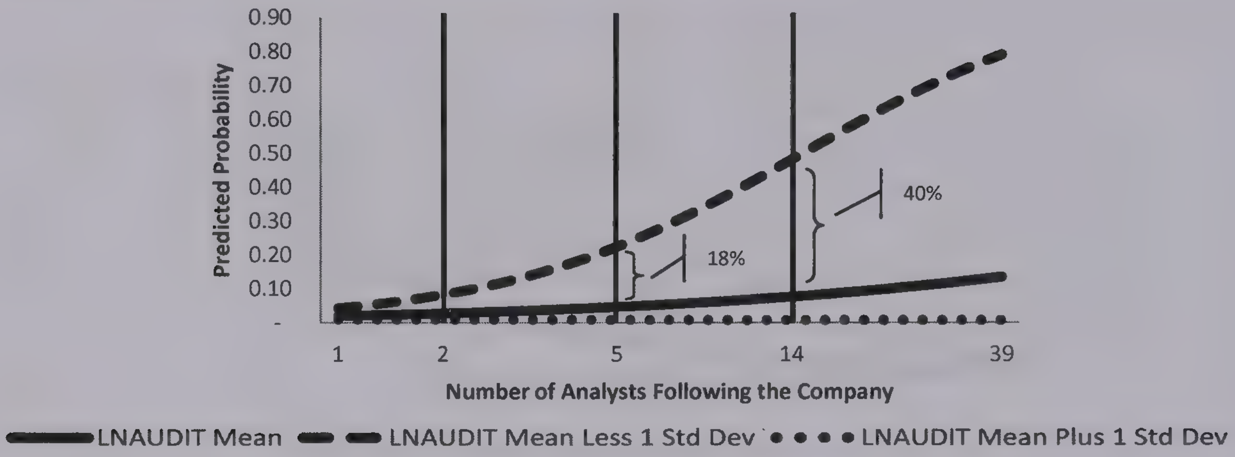
Managers face incentives to meet or beat earnings from their compensation contracts and performance goals (e.g., Burns and Kedia 2006; Efendi et al. 2007). However, Collins et al. (2009) show that companies penalize executives via lower bonuses for both low-quality financial reporting and subsequent restatements. Thus, while compensation contracts provide incentives for aggressive financial reporting, there are also competing incentives for accurate financial reporting (Desai et al. 2006). To examine the effects of compensation contracts on managers' incentives, we re-run the analyses in Table 4 and include the following compensation variables: the ratio of CEO cash bonus to salary, the number of shares owned by the CEO deflated by total shares outstanding, the number of stock options paid to the CEO deflated by total shares outstanding, and the percentage of stock-based CEO compensation. Untabulated results show that these variables are not related to the likelihood of waiving qualitatively material misstatements ($p > 0.10$), with similar results for the hypothesis-testing variables.

V. CONCLUSIONS

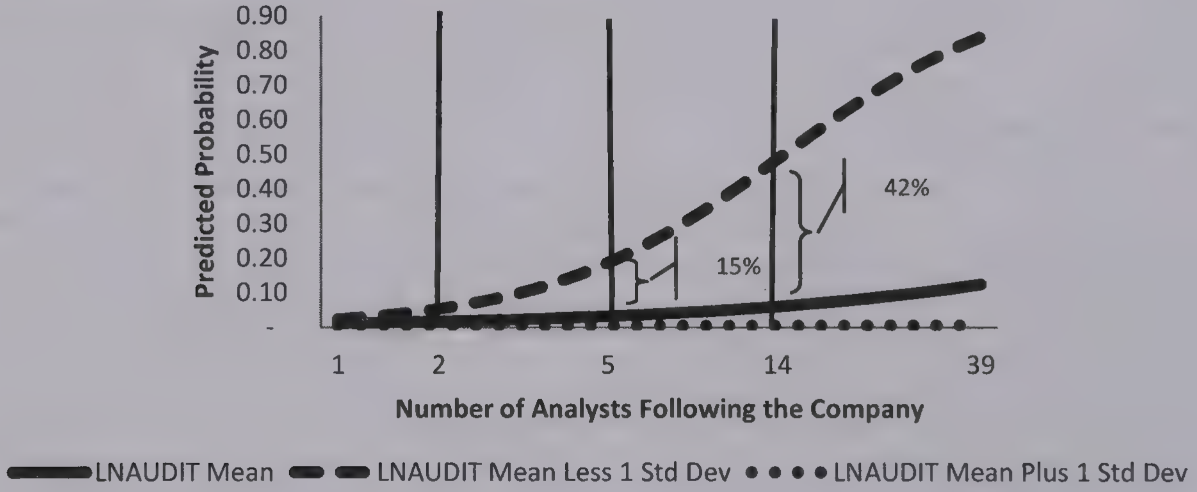
Using data derived from SAB 108 disclosures, we investigate how managers' and auditors' incentives, along with audit committee characteristics, affect qualitative and quantitative materiality judgments about misstatements. We acknowledge certain limitations to our analyses. First, the data include only those disclosures on misstatements that were initially judged immaterial under the regulations in effect at the time of detection and subsequently judged material under SAB 108. There are two other potential misstatement samples: (1) those misstatements that managers and auditors immediately deemed material and corrected upon detection, and (2) those misstatements that were waived when they were detected and that were not subsequently disclosed or corrected under SAB 108 even in instances when managers and auditors judged them to be material. These samples are of obvious theoretical interest, but the data necessary to examine such misstatements are not publicly available. Second, our sample includes a relatively small number of misstatements in relation to the overall number of transactions for public entities during this period, but we note

FIGURE 3 (continued)

Panel B: Model 1b



Panel C: Model 1c



The figures illustrate the effect that increasing *ANALYST*, a logged variable, from its minimum to its maximum at three levels of *LNAUDIT* has on the probability of *QUAL_MATERIAL* = 1. For ease of interpretation, the numbers on the horizontal axis are the unlogged number of analysts following each company. The values represent *ANALYST* at its minimum (1), its mean less one standard deviation (2), its mean (5), its mean plus one standard deviation (14), and its maximum (39). Brackets represent the change that a decrease in *LNAUDIT* from its mean to one standard deviation less than its mean has on the probability of *QUAL_MATERIAL* = 1 at two levels of *ANALYST*.

that other research in this area uses similar samples (e.g., Acito et al. 2009). While SAB 108 disclosure data may be limited to those companies that made such disclosures, such disclosures provide information and insights that would otherwise be unavailable.

We first show that managers are generally more likely to waive qualitatively material misstatements as analyst following increases, but this effect is primarily present when audit fees are relatively low. This finding implies that analyst pressure creates incentives for managers to use aggressive financial reporting in situations in which not correcting a misstatement can allow a company to meet or beat its consensus forecast, and auditors curtail this behavior for high-fee

clients. Thus, we extend prior research that finds that managers use materiality justifications to strategically achieve desirable financial reporting outcomes (Acito et al. 2009).

We next show that auditors are less likely to allow managers to waive both qualitatively and quantitatively material misstatements as audit fees increase. Thus, our results are consistent with the theory of auditor reputation protection, which suggests that auditors make materiality judgments that are consistent with their incentives to avoid second-guessing by regulators and other third parties. We posit that the mechanism through which this occurs is audit effort. Audit fees that are higher overall, higher than "normal," and higher in terms of audit firm importance provide the audit firm greater ability to obtain the evidence necessary to talk managers out of relatively aggressive financial reporting (Kinney et al. 2004). Thus, while higher audit fees may provide incentives for auditors to yield to client pressures, they also increase the visibility of auditors' judgments in this era of publicly available audit fee data and thus increase auditors' incentives to encourage managers to yield to auditor demands for reputation protection when auditors' exposure to that visibility is high. This interpretation is consistent with Bedard and Johnstone (2004), who find a positive association between audit effort, fees, and earnings management risk, which auditors judge to be commonly associated with a history of exactly meeting analysts' consensus forecasts.

The results show further that managers' incentives associated with analyst following are mitigated by auditors' concerns about their own reputations. Specifically, auditors are less likely to allow managers to waive qualitatively material misstatements as audit fees increase. Indeed, the effects of the pressure created by analyst following on managers' waiving of qualitatively material misstatements are primarily associated with clients having relatively low audit fees. These results imply that, during the post-SOX period, a company's economic importance to the audit firm provides auditors with incentives to invest in reputational capital.

Finally, we provide evidence on the role of audit committee oversight, reporting that audit committees with greater finance and accounting expertise are less likely to allow managers to waive material misstatements compared to those with less expertise. Taken together, the results of this study shed light on the complex interplay between analyst following, the pressure that managers face to manage earnings, the pressure that auditors face to protect their reputations in the post-SOX environment, and the important role that audit committees can play in settings in which managers may act strategically to achieve desired financial reporting outcomes.

APPENDIX A

DEPENDENT VARIABLE MEASUREMENTS AND CALCULATIONS: AN EXAMPLE

Panel A: Misstatement Quantification

	12/31/2003	12/31/2004	12/31/2005
Change in Misstatement	−525,000	−500,000	−300,000
Cumulative Misstatement Amount	−525,000	−1,025,000	−1,325,000

"Change in Misstatement" refers to the income statement effect of the misstatement in year *t*. "Cumulative Misstatement Amount" refers to the misstatement amount that has accumulated by the end of year *t*.

Panel B: Qualitative Dependent Variable Measurement

	12/31/2003	12/31/2004	12/31/2005
Misstatement Amount [A]	−525,000	−500,000	−300,000
Common Shares Outstanding for EPS [B]	25,000,000	25,000,000	25,000,000
Misstatement Per Share Amount [C]	−0.02	−0.02	−0.01
Actual EPS Compared to Analyst Forecast [D]	0.03	0.01	0.02
Forecast Error if Misstatement Corrected [E]	0.01	−0.01	0.01
Dependent Variable [F]	0	1	0

Model 1 uses the misstatement amount that affects the income statement in year *t* [A]. We determine the per share misstatement amount [C] by dividing the misstatement amount [A] by the shares outstanding used to calculate earnings per share [B]. Then, we compare the amount by which the company either met or beat analysts' consensus forecast [D] to the per share misstatement amount [C] to arrive at the per share amount by which the company would have met, beat, or missed consensus EPS if it had corrected the misstatement in the current year [E]. If the company would have continued reporting meeting or beating analysts' consensus forecast after correcting the error, then the Model 1 dependent variable (*QUAL_MATERIAL*) is 0 [F]. If the company would have reported missing analysts' consensus forecast after correcting the error, then *QUAL_MATERIAL* is 1.

Panel C: Quantitative Dependent Variable Measurement

	12/31/2003	12/31/2004	12/31/2005
Misstatement Amount [A]	−525,000	−1,025,000	−1,325,000
Income Measure [B]	12,000,000	13,000,000	14,000,000
Misstatement as a Percentage of Income Measure [C]	−4.4%	−7.9%	−9.5%
Dependent Variable [D]	0	1	1

Models 2 and 3 use the larger of the misstatement amount that affects the income statement in year *t* or the misstatement amount that has accumulated by the end of year *t* [A]. We determine the relative percentage of the misstatement to the income measure [C] by dividing the misstatement amount [A] by the income measure [B]. If the misstatement amount is greater than or equal to 5 percent or more of the income measure, then the dependent variable [D] (*QUANT_MATERIAL_NORM* or *QUANT_MATERIAL_PRETAX*) is 1, otherwise it is 0.

Voluntary Disclosure Incentives and Earnings Informativeness

Sugata Roychowdhury
Ewa Sletten
Boston College

ABSTRACT: We propose that the value of the earnings reporting process as an information source lies in limiting delays in the release of bad news, either by inducing managers to disclose it voluntarily or by directly releasing the negative news that managers have incentives to withhold. We compare earnings informativeness in bad-news and good-news quarters. Using returns to measure news, we find, consistent with our prediction, that earnings informativeness relative to other sources is higher in bad-news quarters than in good-news quarters. Further, cross-sectional tests indicate that earnings differential informativeness in bad-news quarters is more pronounced when managers do not voluntarily disclose the news, information asymmetry is stronger, and managers are net sellers of stock.

I. INTRODUCTION

There is a significant literature on the incremental information content of earnings announcements (Beaver 1968; Bamber 1987). More recently, studies such as Ball et al. (2011) and Beyer et al. (2010) argue that the primary value of earnings lies less in releasing

information than in confirming information that has reached the market from alternative sources. Our paper bridges these two (non-mutually exclusive) streams of thought by proposing that the earnings reporting process is geared toward uncovering information that has not as yet been disclosed via alternative sources; in particular, negative information. This "*ex post* settling-up" via earnings is important because it limits managers' ability to delay the release of bad news in two ways. First, the prospect of having to announce earnings at the end of a fiscal period can sometimes induce managers to release bad news voluntarily (Skinner 1997), in which case, the primary role of earnings is confirmation, as in Ball et al. (2011).[1] Second, when managers do not disclose bad news voluntarily, earnings are instrumental in releasing the negative news, and the information content of earnings is important. Overall, the earnings reporting process results in timelier and more precise disclosure of bad news.

We attribute earnings' differential role in revealing bad news relative to good news to managers' voluntary disclosure decisions and the nature of the earnings reporting process. The literature has discussed several possible factors that are likely to provide managers with differential voluntary disclosure incentives with respect to good versus bad news. For example, managers have incentives to preemptively disclose bad news prior to earnings announcements via earnings forecasts over relatively short horizons.[2] Two issues are worth noting in this context. First, short-horizon forecasts are often prompted by the desire to manage the litigation risk and/or the market disappointment arising from the imminent release of the bad news at a forthcoming earnings announcement (Skinner 1994, 1997; Kasznik and Lev 1995; Soffer et al. 2000; Matsumoto 2002; Richardson et al. 2004; Field et al. 2005). Second, besides short-horizon forecasts, voluntary disclosure can also take the form of qualitative disclosures about the firms' operations, press releases about important contracts won or lost, etc. (Miller 2002). Miller (2002) documents that these alternative forms of voluntary disclosures tend to increase (decline) when firm performance improves (deteriorates), suggesting that they are used to convey good news about the firm.[3] In fact, there are a number of reasons discussed in the literature for why managers *delay* disclosures of bad news relative to good news.

Bad-news disclosures are often inherently associated with greater uncertainty in a firm's operations (Li 2006, 2008; Bloomfield 2008; Brown et al. 2009; Ertimur et al. 2011), and tend to be scrutinized more closely by capital market participants. This provides managers with motives to be more precise and careful with their estimates when they disclose bad news, introducing delays in the disclosure. Consistent with this, Graham et al. (2005) document in a survey that top-level executives acknowledge delaying bad-news disclosures to allow themselves time to study and interpret the negative information. Further, negative events often have disproportionately strong implications for stakeholders such as lenders because of asymmetric payoffs in their contracts with the firm (Fama and Miller 1972; Jensen and Meckling 1976). These contracts often rely on earnings performance (Fields et al. 2001; Asquith et al. 2005), increasing the stakeholders' demand for information on the impact of bad news on earnings. As a result, managers may be reluctant to disclose the bad news until they are able to provide a precise estimate of the effect of such news on earnings.

Second, even when the manager is relatively certain about the magnitude of bad news, she may choose to first take corrective action or wait for offsetting good news. In support of this, managers responding to Graham et al.'s (2005) survey admit to delaying bad-news disclosures in the hope that subsequent improvements eliminate the need to make a bad-news disclosure. Third, in some cases, managers can have self-serving motives to delay disclosure of bad news. Kothari et al. (2009) propose that managers' concerns about their careers, compensation packages, and stock-price-based wealth provide them with incentives to disclose good news early and delay bad-news disclosures.

---

[1] Our evidence suggests that managers prefer to preemptively disclose negative information rather than wait for the earnings announcement, when the magnitude of the negative news is particularly large.

[2] Managers may also expedite bad news disclosures and delay good news disclosures out of a desire to obtain lower option exercise prices prior to option grants (Yermack 1997; Aboody and Kasznik 2000).

[3] Short-horizon forecasts exhibit a reverse pattern, consistent with such forecasts primarily conveying bad news.

The earnings reporting process plays an important role in the context of delayed voluntary disclosures of bad news. GAAP measurement principles provide guidelines for how to estimate and report losses in future cash flows via earnings components such as warranty and bad debt expenses, asset write-downs, etc. (Basu 1997). These measurement principles provide managers with tools for arriving at more precise estimates of bad news and their impact on earnings. Further, earnings reports are scrutinized by external fiduciary agents such as outside directors, auditors, and regulators. The checks and balances incorporated in the earnings reporting process imply that at least some news that has not been previously disclosed is likely to be released in earnings. Finally, earnings releases are closely scrutinized by investors and financial analysts. In particular, during earnings-related conference calls, analysts and investors question managers about the future implications of current earnings (Tasker 1998; Frankel et al. 1999). The evidence in Matsumoto et al. (2011) indicates that these conference calls are more informative when earnings announcements convey negative news. Further, the greater information content is more a result of scrutiny by capital market participants, such as financial analysts, rather than voluntary disclosures by managers.

In summary, if there are intra-quarter delays in the disclosure of bad news, then the announcement of earnings is expected to reveal at least some of the delayed bad news, with two possible consequences. In certain cases, for example, when the news is particularly negative, managers are prompted by its imminent release at earnings announcements to voluntarily disclose the news prior to the announcement. In the majority of cases when the news is not particularly negative and/or the litigation risk is not high enough to warrant early disclosure, the bad news is conveyed at the time of the earnings announcement. Consequently, when the overall news reaching the market in a quarter is negative, we expect it to be more concentrated around the announcement of earnings at quarter-end than when it is positive, particularly in instances that we observe no issuance of short-horizon forecasts.[4]

In our empirical analysis, we define an announcement quarter as extending from the end of the previous quarter's earnings announcement to the end of the current quarter's earnings announcement. Incremental news released by earnings is captured by returns in the three days around the current quarter's earnings announcement date. We compare the news that reaches the market during the three-day quarterly earnings announcement (QEA) window to that reaching the market during the non-QEA period in the quarter to determine earnings incremental informativeness relative to other information sources. Using a sample of 152,275 firm-quarters over the period 1987–2006, we find that earnings informativeness is higher in bad-news quarters than in good-news quarters.[5] The result is robust to using ranked values of our independent variable to address the issue of outliers, and to controlling for various factors, including firm fixed effects and any potential mechanical bias in our empirical measure. As predicted, earnings differential informativeness in bad-news quarters is concentrated among firm-quarters without short-horizon forecasts.

---

[4] Importantly, the role of earnings with respect to negative versus positive information, which we examine empirically, is distinct from the one examined by Basu (1997). We focus on earnings' role in the *release* of bad news relative to good news, while Basu (1997) measures earnings' greater timeliness in *recognizing* bad news that may already have been released by other information sources.

[5] For the overall sample, the ratio of news released around QEAs to that in non-QEA periods is around 18 percent for bad-news periods and around 16 percent for good-news periods; that is, earnings are around 12 percent more informative in bad-news quarters.

Our cross-sectional analysis focuses on examining two situations in which earnings are a particularly important source of bad news. First, we predict that earnings play a more pronounced role in the release of bad news among firms with greater information asymmetry between managers and external investors. In such firms, managers are more likely to delay voluntarily releasing negative news, either because their private information is less observable to investors or because the magnitude of bad news is less measurable pending the completion of the earnings reporting process. Second, in periods in which managers sell stock, disclosures of bad (good) news would lead to more unfavorable (favorable) trade outcomes, making it more likely that managers delay disclosures of bad news relative to those of good news.[6] Thus, we predict that earnings differential informativeness is more pronounced among firm-quarters with net insider sales of stock. Our results support our predictions and indicate significant cross-sectional effects. When information asymmetry is in the highest decile (when there are net insider sales), the informativeness of earnings in bad-news quarters is higher than that in good news quarters by as much as 38 percent (23 percent).

In further tests, we find a non-monotonic pattern in earnings differential informativeness across the fiscal quarters, with a peak in the third quarter and a slight decline thereafter in the fourth quarter. We interpret the results as indicating a rise in earnings differential informativeness as the year-end audit approaches over the first three fiscal quarters. However, more intensified efforts at gathering information by market participants in the fourth quarter in anticipation of the imminent release of audited annual results, and more voluntary disclosures by managers in response possibly diminish the role of earnings as a disclosure medium in the fourth quarter.[7] In sensitivity analyses, we find that earnings' differential informativeness persists after excluding firm-quarter observations in which QEAs are accompanied by management forecasts.

The informativeness of earnings has received considerable attention in recent times. The verification and measurement rules underlying financial reporting, along with the scrutiny by fiduciary agents such as auditors and boards of directors, are generally thought to make earnings numbers untimely relative to other information sources and, hence, less informative (Ball and Shivakumar 2008; Ball et al. 2011; Beyer et al. 2010). Our findings indicate that earnings value as an information source does not arise solely from the absolute amount of news that earnings convey to the market. Instead, earnings' incremental usefulness lies in limiting delays in the release of negative news, either by inducing managers to disclose it voluntarily or by directly releasing the bad news that managers withhold. In either case, earnings' information role as discussed in this paper should be of particular interest to standard-setters as they establish fresh measurement principles under the new conceptual framework.

In Section II, we develop our hypotheses. Section III describes the data, empirical design, and descriptive statistics. Section IV discusses primary results, and Section V presents additional analyses. Section VI concludes.

II. HYPOTHESES DEVELOPMENT

Earnings Differential Informativeness

The literature discusses a number of circumstances under which managers can delay disclosures of bad news relative to those of good news. The earnings reporting process can limit delays in the release of negative news in two ways. First, the prospect of the eventual release of bad news at the time of the earnings announcement can induce managers to voluntarily disclose the bad news; for example, out of concern for litigation risk. To the extent that bad news remains undisclosed, as is possible when perceived litigation risk is low and/or managers' incentives to delay are more pronounced, the news is released at the time of the earnings announcement. Managers' disclosure incentives and the earnings reporting process are discussed in greater detail below, along with our empirical predictions.

---

[6] There is considerable evidence that firm insiders possess private information at the time they sell stock (Seyhun 1986; Beneish and Vargus 2002; Ke et al. 2003; Piotroski and Roulstone 2005).

[7] For example, Baginski and Hassell (1990) report that not only do managers issue more forecasts during the fourth quarter, but also that fourth-quarter management forecasts are more influential in generating revisions in analyst estimates of future earnings relative to other quarters.

Greater scrutiny by capital markets upon bad-news disclosures, and additional demand for information on the impact of the bad news on earnings from debtholders (Fama and Miller 1972; Jensen and Meckling 1976), can make managers reluctant to disclose the bad news until they can arrive at more precise estimates of its impact. Second, upon observing bad news, managers can take corrective action or wait for offsetting good news before releasing the news to the market (Graham et al. 2005). Finally, a desire to capture private benefits or sustain higher firm valuations can make managers unwilling to disclose bad news immediately (Sletten 2012), consistent with the "stockpiling" of negative information referred to in Hutton et al. (2009). Such motives to delay bad-news disclosures can arise from managers' career and wealth-related concerns (Kothari et al. 2009), or from the tendency to "hype the stock" prior to capital market events such as seasoned equity offerings (Lang and Lundholm 2000).[8]

Disclosure of bad news that has not yet been released through other channels, including voluntary disclosures, is likely at the QEAs for a number of reasons. First, unlike most voluntary disclosures, such as management forecasts, financial statement information is scrutinized by outside directors and auditors before the earnings release. Auditors' and outside directors' reputations are tied to their ability to uncover adverse information. Failure to do so can result in lawsuits and regulatory penalties in addition to reputation loss, as with Arthur Andersen's failure to highlight irregular accounting practices at Enron in 2001. Second, financial reporting by listed firms is regulated, with costs for firms and managers via regulatory investigations, restatements, and personal penalties if accounting practices deviate significantly from acceptable norms (Dechow et al. 1996; Feroz et al. 1991; Palmrose et al. 2004). The checks and balances imposed on financial statements imply that to the extent that bad news affects contemporaneous earnings, managers' ability to conceal it, particularly across multiple successive periods, is likely limited (Xie 2001; Barton and Simko 2002). Finally, GAAP measurement rules provide a framework for the estimation of future cash flow losses based on managers' private information when reporting earnings, for example, via bad debt provisions, warranty expenses, inventory write-offs, etc. Such conservative measurement rules (Watts and Zimmerman 1976; Watts 2003) can amplify the role of earnings reports in releasing bad news.[9]

Delayed disclosures of bad news relative to good news, GAAP measurement principles and practices, and the checks and balances characterizing the earnings reporting process will result in earnings playing a greater role in the release of bad news than good news. Specifically, we predict that a greater proportion of news reaching the market in a given quarter is released at the time of the earnings announcement when the news is negative than when the news is positive. We use the sign of the quarterly return to proxy for the sign of the news reaching the market during the quarter. Earnings informativeness is measured as the proportion of news reaching the market at the time of the QEA relative to that during the non-QEA period in that quarter. Our first hypothesis can be formally stated as follows:

---

[8] In a slightly different context, Miller (2002) points out that the general desire to maintain high valuations makes it more likely for firms to issue disclosures when they are experiencing performance gains than when they are experiencing performance declines.

[9] A substantial literature argues that conservative reporting and auditing practices arise in equilibrium as an offsetting mechanism to any propensity of managers to delay the release of bad news relative to that of good news (Devine 1963; Watts and Zimmerman 1976; Antle and Nalebuff 1991).

> **H1:** Earnings informativeness is higher when the overall news reaching the market during a quarter is negative than when it is positive.

We emphasize that H1 is based on earnings releasing new negative information to investors, rather than on recognizing negative information that investors are already aware of. Basu (1997) describes how one implication of conservatism in reporting and auditing practices is the asymmetric timeliness of earnings in recognizing bad news relative to recognizing good news. The key difference between the differential informativeness of earnings and asymmetric timeliness as investigated by Basu (1997) is that the former attempts to capture the timing of the news release within the quarter, while the latter does not. Specifically, earnings informativeness as measured in this paper is higher when the proportion of news released at the time of the QEA relative to the non-QEA period is greater. However, earnings asymmetric timeliness can be high even if all news in the quarter reaches the market prior to the QEA, but earnings *recognize* the bad news in a timelier manner than the good news. In a study that investigates earnings' incremental information content, McNichols (1988) documents that earnings announcement returns are less positively skewed than returns during similar-length windows in non-announcement periods. However, she also reports that the frequency of negative announcement returns is lower than that of negative non-announcement-period returns. As a result, this evidence is insufficient to conclude whether earnings are a more important source of bad news than good news.

Cross-Sectional Variation

In this section, we discuss cross-sectional predictions arising from H1. Our primary cross-sectional analyses focus on identifying situations in which bad news revelations from information sources other than earnings (e.g., voluntary disclosures) are likely to be limited. We focus on two cross-sectional partitions based on: (1) information asymmetry, and (2) net sale of stock by insiders.

With greater information asymmetry between managers and external investors, investors are less likely to be cognizant of managers' privately observed news, providing managers with greater opportunities to delay the release of negative private information. We expect information asymmetry between managers and investors to be higher among firms with smaller size, lower analyst following and institutional ownership, lower liquidity, and greater idiosyncratic volatility (Collins et al. 1987; Foster and Viswanathan 1993; Bushee and Noe 2000; Jiang et al. 2005). Such firms are also likely to operate in economic environments characterized by greater uncertainty. Greater uncertainty, in turn, can make managers delay disclosures of bad news until the earnings reporting process generates more precise estimates of bad news. In either case, we predict that the greater the information asymmetry, the more pronounced is the role of earnings in disclosing bad news relative to good news.

> **H2:** Earnings differential informativeness during bad-news quarters relative to good-news quarters is higher among firms with greater information asymmetry.

Our primary hypothesis (H1) does not necessarily require that managers are opportunistic or strategic with respect to their own short-term monetary incentives. The delays in bad-news disclosures could arise from perceived benefits of measuring the bad news with greater precision or attempting to reverse the bad news. However, managers' incentives can also be self-serving, as when managers are net sellers of stock in a given period. There is significant evidence in the literature that at the time of insider trades, managers possess undisclosed private information (Seyhun 1986; Noe 1999; Ke et al. 2003), particularly regarding future earnings (Beneish and

Vargus 2002; Piotroski and Roulstone 2005). We expect that managers' incentives to delay disclosures of any negative information they possess are stronger in the quarters in which they are also net sellers of stock. We accordingly test whether earnings' incremental role in releasing bad news relative to good news is more pronounced in firm-quarters with net insider sales.

H3: Earnings' differential informativeness during bad-news quarters relative to good-news quarters is higher in quarters with net insider sales of firm stock.

III. DATA, EMPIRICAL PROXIES, AND DESCRIPTIVE STATISTICS

Data

To construct our sample, we begin with all firm-quarters in Compustat with earnings announcement dates, and sufficient data to calculate market value of equity (MVE), book value, and leverage. We also require daily returns data from CRSP to compute quarterly returns, earnings announcement returns, and idiosyncratic return volatility. Analyst following is obtained from I/B/E/S, while institutional ownership and insider trade data are obtained from Thomson Financial, and are set equal to 0 when not available. Finally, bid-ask data are obtained from the Institute for the Study of Security Markets database (ISSM) for years 1987–1992, and from the NYSE Trades and Quotes database (TAQ) for years 1993–2006. Since common coverage in these databases starts in 1987, our sample includes 152,275 firm-quarters over the 80 quarters from 1987 to 2006, and comprises 10,204 individual firms. In additional tests, we supplement our data with management forecasts obtained from First Call. Since First Call provides little coverage in early years, our additional tests incorporate firm-quarters starting from 1995.

Measuring Informativeness of Earnings Announcements

We measure news using equity returns.[10] Earnings announcement returns (EAR_t) are defined as the market-adjusted buy-and-hold returns over the three days from Day −1 to Day +1, where Day 0 is the quarterly earnings announcement (*QEA*) date. Quarterly returns (RET_t) are defined as the market-adjusted buy-and-hold returns starting two days after the earnings announcement of Quarter $t-1$ and ending one day after the announcement of Quarter t.[11] The mean length of the period over which RET_t is computed is around 63 trading days. Non-earnings-announcement returns ($NEAR_t$) are estimated as $(1 + RET_t)/(1 + EAR_t) - 1$.[12]

---

[10] Returns are a comprehensive measure of news released both by earnings and by other sources in the non-earnings-announcement period. Returns around earnings announcements capture both the information released by earnings itself, as well as the additional information managers often release with earnings announcements (including that via conference calls) to facilitate understanding of the implications of earnings information (Chen et al. 2002; Frankel et al. 1999). Further, during the non-earnings-announcement period, returns capture the net information released by various sources: alternative forms of managerial disclosures such as earnings forecasts and non-earnings-related qualitative disclosures, as well as information searches by third parties such as financial analysts.

[11] We require at least 25 days with trading to compute *RET*. The market adjustment involves subtracting the buy-and-hold return on the CRSP value-weighted market index from the corresponding buy-and-hold return of the firm. We also conducted robustness analyses with size and book-to-market adjusted returns, instead of market-adjusted returns. This adjustment involves partitioning firms into five equal groups of size and book-to-market, thus, yielding 25 size and book-to-market portfolios. The adjusted return for a firm is then the daily raw return in excess of the daily return on the matching size and book-to-market portfolio. All our subsequent results, including those we obtain in the cross-sectional tests, are robust to using this alternative adjustment.

[12] We check the robustness of our analysis to two alternative definitions of the earnings announcement window. In the first, we estimate *EAR* over Day −3 to Day +3 with respect to the QEA. In the second, we acknowledge that a longer window is especially suitable for smaller firms, and estimate *EAR* over Day −3 to Day +3 for firms below median size, while using Day −1 to Day +1 for firms above median size. In both specifications, the estimation of *NEAR* is adjusted accordingly. All our results are robust to both of these specifications.

n of firm-quarters	152,275	77,723	74,552	152,275	77,723	74,552

Table 1 provides descriptive statistics for *NEWS_RATIO* and *Ln(NEWS_RATIO)*.

Variable Definitions:
NEWS_RATIO = 100 ∗ *ABS*(*EAR*)/*ABS*(*NEAR*);
ABS(*EAR*) = absolute value of cumulative market-adjusted returns on trading days −1 to +1 relative to the QEA date;
ABS(*NEAR*) = the absolute value of the cumulative market-adjusted non-earnings-announcement period returns;
Ln(*NEWS_RATIO*) = natural logarithm of *NEWS_RATIO*; and
BNEWS = an indicator variable equal to 1 if overall quarterly return *RET* is negative, and 0 otherwise.

We measure earnings informativeness using a ratio of the news arriving during the QEAs to that arriving during non-QEA periods, denoted as *NEWS_RATIO* and defined as 100 ∗ *ABS*(*EAR*)/*ABS*(*NEAR*). The ratio expresses the absolute value of market-adjusted QEA returns, *ABS*(*EAR*), as a percentage of the absolute value of market-adjusted returns during non-QEA periods, *ABS*(*NEAR*).[13]

We expect *NEWS_RATIO* to be high during quarters when the overall news (measured by quarterly return, *RET*) is negative relative to when overall news is positive. Our prediction is easy to follow if *EAR* and *NEAR* are always of the same sign. When *EAR* and *NEAR* are of differing signs, the analysis is more involved, but *NEWS_RATIO* is still expected to exhibit the same asymmetry. Specifically, for all observations consistent with our hypotheses, *NEWS_RATIO* is expected to be systematically higher in negative-return periods ($RET < 0$) and lower in positive-return periods ($RET > 0$). In contrast, for all observations inconsistent with our hypotheses, *NEWS_RATIO* is expected to exhibit the reverse pattern. Thus, variation in *NEWS_RATIO* is well suited to testing whether earnings informativeness is higher when overall information reaching the market is negative. This is discussed in greater detail in Appendix A.

Table 1 presents the details of the distribution of *NEWS_RATIO* and its logarithmic transformation *Ln*(*NEWS_RATIO*) for the overall sample, as well as separately for bad-news and good-news quarters. For every firm, good-news and bad-news quarters are identified by the sign of overall quarterly return, *RET*, and characterized by the indicator variable $BNEWS_t$, which is set equal to 1 if $RET_t < 0$, and is equal to 0 otherwise. Thus, $BNEWS_t = 1$ corresponds to bad-news quarters, while $BNEWS_t = 0$ identifies good-news quarters.

---

[13] *NEWS_RATIO* is unlikely to be affected systematically by post-earnings-announcement drift (PEAD) or the under-reaction of the market to current-period dollar earnings surprises (Foster et al. 1984). PEAD implies that earnings surprises at the time of the QEAs predict returns in the following period; further, most of the "drift" return is realized at the subsequent QEAs (Bernard and Thomas 1989). Thus, in the period of the initial earnings surprise, PEAD is likely to bias our measure of earnings informativeness downward; in the period following the initial earnings surprise, PEAD is more likely to bias the measure upward. The overall effect of drift on *NEWS_RATIO* is, thus, ambiguous, and even more so when we subsequently partition on the sign of the returns.

We winsorize *NEWS_RATIO* at the 1st and 99th percentiles, as it includes some unrepresentative high-magnitude ratios driven by low denominators. However, the sharp difference between mean and median *NEWS_RATIO* in Table 1 for the overall sample and both subsamples implies that the variable remains right-skewed. To further address this issue, we compute the natural logarithm of the ratio, denoted *Ln*(*NEWS_RATIO*), and use this measure in our primary empirical tests. As can be seen from the proximity of mean and median *Ln*(*NEWS_RATIO*), the variable is symmetrically distributed. Finally, as an alternative to computing the natural logarithm of the ratio, we supplement our primary tests with additional regressions in which we use decile ranks of *NEWS_RATIO* (*Ranked NEWS_RATIO*) as the dependent variable.

NEWS_RATIO and *Ln*(*NEWS_RATIO*) for $BNEWS = 1$ exceeds that for $BNEWS = 0$ for all the percentiles listed in the table, except for the 95th and 99th percentiles. The median *NEWS_RATIO* is greater for bad-news quarters, but the opposite is true based on the mean ratio, a result of the variable's right-skewness.[14] Computing the natural logarithm of the ratio smoothes out the distribution, and both medians and means produce similar results; i.e., *Ln*(*NEWS_RATIO*) is greater in bad-news quarters. We conduct and discuss formal tests of significance of the difference in means and medians, as well as interpret the magnitude of *Ln*(*NEWS_RATIO*), in Section IV.

Measuring Information Asymmetry

We are primarily interested in a measure of information asymmetry that captures circumstances in which voluntary disclosures of bad news are less timely. A number of variables have been used in the literature to proxy for the information environment in various settings.

Firms with greater size and larger analyst following are expected to be characterized by less information asymmetry between managers and investors, a consequence of both market participants' greater efforts to uncover information and managers' greater willingness to be forthcoming with information (Collins et al. 1987). Further, there is evidence that institutional ownership is positively associated with firm disclosure quality (Bushee and Noe 2000). Thus, we expect that firms with higher institutional ownership are likely to have lower information asymmetry. Greater firm-level return volatility is generally reflective of greater uncertainty about a firm's operations (see, for example, Jiang et al. 2005). While this uncertainty can affect both managers and investors, it is likely to make any managerial information advantage less detectable *ex post* by external investors. Uncertainty about a firm's operations may also result in the manager requiring more time to arrive at a precise estimate of bad news. Another widely used measure of information asymmetry is the adverse selection component of the bid-ask spread (Foster and Viswanathan 1993; Brennan and Subrahmanyam 1996). It measures the extent to which the bid-ask spread quoted for the firm reflects the market makers' attempts to protect themselves against informed trading.

Instead of using the five variables separately, we use principal components analysis to extract the common variation in these variables. The five variables include: (1) logarithm of firm size, defined as market value of equity (*SIZE*), (2) logarithm of 1 plus analyst following, defined as the number of analysts covering the firm (*NUM_AN*), (3) institutional ownership, or the percentage of outstanding shares owned by institutions (*INST_OWN*), (4) idiosyncratic return volatility (*IVOL*), and (5) the adverse selection component of the bid-ask spread (*Adv_BidAsk*). *IVOL* is computed as the volatility of daily firm returns in excess of market returns in the preceding quarterly period, but excluding the earnings announcement. In computing *Adv_BidAsk*, we follow Brennan and Subrahmanyam (1996), who estimate the sensitivity of price changes to order flow based on a model of price formation developed by Hasbrouck (1991). It is computed as the daily average over the last month of the preceding quarter.[15]

---

[14] The relatively few instances in which managers pre-announce negative information are likely to dampen the mean *NEWS_RATIO* for bad-news quarters. This is analyzed in greater detail in Section IV.

The principal components analysis yields a composite measure of information asymmetry between managers and shareholders, denoted *InfoAsymm*. *InfoAsymm* is negatively associated with *SIZE*, *NUM_AN*, and *INST_OWN*, and positively associated with *IVOL* and *Adv_BidAsk*. Thus, higher values of the composite measure *InfoAsymm* represent greater information asymmetry. To facilitate our cross-sectional analyses, we rank firms into deciles of *InfoAsymm* every quarter. Using the ranked variable allows us to measure earnings informativeness within each decile, and to provide a more intuitive interpretation of variation in earnings informativeness across the deciles.

Firm Characteristics: Variable Definitions and Descriptive Statistics

Table 2, Panel A, presents the key descriptive statistics for the sample, including the pooled mean, median, standard deviation, and the 5th and 95th percentiles. All continuous variables are winsorized at the 1 percent level. Additionally, we present variation in these descriptive statistics across good-news ($BNEWS_t = 0$) and bad-news quarters ($BNEWS_t = 1$) in Table 2, Panel B. For the purposes of assessing statistical significance of the differences, we use t-statistics with standard errors clustered by firm and fiscal year-quarter for the means, and Z-statistics from the Wilcoxon rank-sum tests for the medians.

RET is measured over the entire quarter (63 trading days, on average). The non-earnings-announcement period return, *NEAR*, spans, on average, a 60-day trading period, excluding the three days around the QEA date and, hence, corresponds closely to *RET*. Mean magnitudes of *RET*, *EAR*, and *NEAR* are higher than the corresponding medians in both the good-news and bad-news quarters, indicating positive skewness in the magnitudes. Both the mean and median magnitudes of earnings announcement returns, *ABS*(*EAR*), are significantly larger in bad-news quarters than in good-news quarters. The mean and median magnitudes of non-announcement returns, *ABS*(*NEAR*), on the other hand, are significantly lower during bad-news quarters than good-news quarters.

Highlighting that earnings are more likely to convey adverse information during bad-news quarters, negative three-day earnings announcement returns tend to occur significantly more frequently in quarters with negative *RET*. Mean *BAD_EAR*, an indicator variable set equal to 1 if $EAR < 0$, is 59.3 percent in bad-news quarters and 39.8 percent in good-news quarters. Mean number of trading days in the announcement quarter, denoted *TRADE_DAYS*, is between 63–64 days and significantly higher for bad-news quarters. This finding is consistent with evidence in the prior literature that documents that earnings announcements tend to be delayed when there is bad news to be conveyed (Givoly and Palmon 1982; Patell and Wolfson 1982; Chambers and Penman 1984; Cohen et al. 2007).

The bad-news subsample includes firms with significantly lower size, measured using market value of equity (*MVE*). Firms in the bad-news subsample also have significantly lower analyst following and institutional ownership, while exhibiting significantly greater idiosyncratic return volatility. *BTM* is the ratio of the book value of equity to market value of equity, and financial leverage, *LEV*, is computed as the ratio of total debt to total assets. All firm characteristics are measured at the beginning of the period. The descriptive statistics demonstrate that while *BTM* is significantly lower for firms in the bad-news subsample, leverage is similar across the two samples.

---

TABLE 2 (continued)

*, **, *** Represent statistical significance at a minimum 0.1, 0.05, and 0.01 levels, respectively.
Table 2 presents descriptive statistics. Panel A reports descriptive statistics for the full sample of 152,275 firm-quarters from 1987–2006. P5 and P95 are the 5th and 95th percentiles, respectively. Panel B reports means and medians for two subsamples: (1) firm-quarters with negative abnormal returns (*BNEWS* = 1), and (2) firm-quarters with positive abnormal returns (*BNEWS* = 0). For the purposes of assessing statistical significance of the differences, we use t-tests with standard errors clustered by firm and year-quarter for the means, and Z-statistics from the Wilcoxon rank-sum test for the medians.

Variable Definitions:
RET = quarterly market-adjusted returns beginning two days after the quarterly earnings announcement for the previous quarter and ending one day after the final earnings announcement for the current quarter;
BNEWS = an indicator variable equal to 1 if *RET* is negative, and 0 otherwise;
EAR = cumulative market-adjusted returns on trading days −1 to +1 relative to the quarterly earnings announcement;
NEAR = cumulative market-adjusted non-earnings-announcement period returns (spanning all trading days included in *RET* except for the trading days included in *EAR*);
ABS(*RET*), *ABS*(*EAR*), and *ABS*(*NEAR*) = absolute values for *RET*, *EAR*, and *NEAR*, respectively;
BAD_EAR = an indicator variable set equal to 1 if *EAR* < 0;
TRADE_DAYS = number of trading days in the announcement quarter;
MVE = beginning-of-quarter market value of equity;
NUM_AN = beginning-of-period number of analysts following the firm;
INST_OWN = beginning-of-period percentage institutional ownership;
IVOL (idiosyncratic volatility) = volatility of daily firm returns in excess of market returns in the preceding quarterly period, excluding the earnings announcements;
Adv_BidAsk = adverse selection component of the daily bid-ask spread (based on Hasbrouck [1991]) computed as the daily average over the last month of the preceding quarter;
BTM = beginning-of-period book-to-market ratio (book value of equity to market value of equity);
LEV = beginning-of-period leverage measured using ratio of total debt, both long-term and short-term, to total assets;
HITECH = binary indicator variable that is set equal to 1 if the firm belongs to any of the following four-digit SIC industry codes: 2833–2836, 3570–3577, 3600–3674, 7371–7379, or 8731–8734;
INSALE = binary indicator set equal to 1 for firm-quarters with net insider sales, and 0 otherwise. Net insider sales are measured as the sales of stock minus purchases of stock across directors and firm executives identified as officers; and
BIAS_ADJ = natural logarithm of the ratio of cumulative market-adjusted returns during a random three-day window in the quarter relative to the cumulative market-adjusted returns during that quarter outside the window.

Following Field et al. (2005), we define *HITECH* as a binary indicator variable that is set equal to 1 if the firm belongs to the following four-digit SIC industry codes, signifying technology-intensive industries: 2833–2836 (drugs and pharmaceuticals), 3570–3577 (computer and office equipment), 3600–3674 (electrical equipment and electronics), 7371–7379 (software services) or 8731–8734 (R&D services). As the mean value of *HITECH* shows, 24.9 percent of the bad-news firm-quarters and 23.1 percent of the good-news firm-quarters belong to technology-intensive industries. Finally, *INSALE* is a binary 0/1 indicator set equal to 1 if insiders have net sales of stock in a given firm-quarter. Net insider sales are measured as the stock sales minus stock purchases across directors and firm executives identified as officers.[16] Table 2, Panel B, indicates that insider sales are significantly less frequent in bad-news quarters, where their frequency is around 31.1 percent, than in good-news quarters, where their frequency is around 35.5 percent.

For every firm-quarter in our sample, we identify a random three-day window and measure the ratio of news released in that window to that released in the period within that quarter outside of the three-day window.[17] The natural logarithm of this ratio is used in our multivariate analyses to control for possible mechanical bias in our dependent variable, and is denoted *BIAS_ADJ*. This is further discussed in Section IV. As Table 2, Panel B, reports, mean and median *BIAS_ADJ* are significantly higher in bad-news quarters than in good-news quarters. Table 2 demonstrates that significant differences can exist in the characteristics of firms that experience negative versus positive returns, particularly those such as size and book-to-market, which are likely associated with firm risk. To address the issue of systematic differences, we control for these firm characteristics in our regression analyses, discussed below.

---

[16] We exclude divisional officers and officers of subsidiary companies in estimating net insider sales.
[17] The random three-day window excludes any of the three days around the QEA.

IV. PRIMARY ANALYSES

Earnings Informativeness and the Sign of News

In our first empirical test of H1, we make univariate comparisons between the mean and median earnings informativeness (*Ln*(*NEWS_RATIO*)) across bad- and good-news quarters. To assess the difference in means, we use two types of t-tests with (1) standard errors clustered by firm and fiscal year-quarter, and (2) bootstrapped standard errors.[18] The difference in medians is evaluated based on the Z-statistic from the Wilcoxon rank-sum test. We report the results of these tests in Table 3, Panel A. Consistent with H1, mean and median *Ln*(*NEWS_RATIO*) are higher for bad-news quarters than for good-news quarters, with the differences being statistically significant at the 1 percent level. For both the $BNEWS = 1$ and $BNEWS = 0$ subsamples, we compute implied *NEWS_RATIO*, which is simply the exponent of the corresponding *Ln*(*NEWS_RATIO*). The implied *NEWS_RATIO* using the mean logged ratio is around 34.5 percent for bad-news quarters and 30.4 percent for good news quarters. The interpretation of this finding is that earnings are 13.5 percent more informative in bad-news quarters than in good-news quarters.

We next shift to multivariate tests. We use the following two regressions to test whether the news released during quarterly earnings announcements (QEAs) relative to that released during non-announcement (non-QEA) periods is greater when the overall returns are negative:

$$Ln(NEWS\_RATIO_t) = \alpha_0 + \beta * BNEWS_t + \alpha_1 * BIAS\_ADJ_t + \varepsilon_t. \tag{1}$$

$$\begin{aligned} Ln(NEWS\_RATIO_t) = {} & \alpha_0 + \beta * BNEWS_t + \alpha_1 * BIAS\_ADJ_t + \alpha_2 * RInfoAsymm_{t-1} + \alpha_3 * INSALE_t \\ & + \alpha_4 * TRADE\_DAYS_t + \alpha_5 * RBTM_{t-1} + \alpha_6 * RLEV_{t-1} + \alpha_7 * HITECH_{t-1} \\ & + \varepsilon_t. \end{aligned} \tag{2}$$

The intercept α_0 in Equation (1) represents the mean *Ln*(*NEWS_RATIO*) for good-news quarters after controlling for *BIAS_ADJ*. The coefficient on *BNEWS*, β, captures the extent to which the *Ln*(*NEWS_RATIO*) ratio is different for bad-news quarters as compared to good-news quarters. Our primary hypothesis (H1) predicts that the *Ln*(*NEWS_RATIO*) is higher when overall quarterly return, *RET*, is negative. In other words, we predict that β is significantly positive.

Equation (1) represents a restricted model in which we include only one control variable, *BIAS_ADJ*. It is possible that variation in *Ln*(*NEWS_RATIO*) across bad-news and good-news quarters arises at least partially from the differing variances of negative quarterly returns and positive quarterly returns.[19] However, differing variances of negative and positive returns should influence the informativeness we observe for any random three-day window within the quarter, not

---

[18] The bootstrapped standard errors come from re-sampling 152,275 observations 1,000 times with replacement.

[19] While the computation of *NEWS_RATIO* does not involve *RET per se*, it does involve returns during the non-QEA window in the quarter (*NEAR*). Since *NEAR* is highly associated with *RET* (correlation coefficient of 0.94), systematic differences in the variance of positive versus negative *RET* can mechanically induce systematic differences in *NEWS_RATIO* across the positive-*RET* and negative-*RET* partitions.

TABLE 3 (continued)

Table 3 presents univariate and multivariate tests of earnings differential informativeness. Panel A includes univariate t-tests for the differences of means and median of *Ln*(*NEWS_RATIO*) between the bad-news and the good-news quarters (*BNEWS* = 1 versus *BNEWS* = 0). t-tests are used for the comparison of the means, and the Z-statistic from the Wilcoxon rank-sum for the comparison of the medians. The first t-statistic is based on standard errors clustered by firm and fiscal year-quarter, while the second is based on bootstrapped standard errors clustered by fiscal year-quarter (obtained from drawing 152,275 observations 1,000 times with replacement). Panel B, Models 1, 2, and 4, report the results of OLS regressions with standard errors clustered by firm and fiscal year-quarter, while Panel B, Model 3, reports OLS regression results with firm fixed effects and clustering of standard errors by fiscal year-quarter. In all the regression models in Panel B (except for Model 4), we use *Ln*(*NEWS_RATIO*) as the dependent variable. In Panel B, Model 4, the dependent variable is the decile rank of *NEWS_RATIO* (*Ranked NEWS_RATIO*). Implied Ratio is the exponent of the predicted *Ln*(*NEWS_RATIO*), obtained by setting all control variables to their means except for *BIAS_ADJ*, which is set equal to 0, and *BNEWS*, equal to 1 or 0. Panel C reports the results of OLS regressions with *Ln*(*NEWS_RATIO*) as the dependent variable, and with standard errors clustered by firm and fiscal year-quarter. Panel C, Model 1, includes the sample of 134,658 firm-quarters between 1995 and 2006. Panel C, Model 2, includes the subsample of 14,152 firm-quarters between 1995 and 2006 that issue forecasts of current earnings following the previous quarter's earnings announcements, or short-horizon forecasts. Panel C, Model 3, includes the subsample of 120,506 firm-quarters between 1995 and 2006 that do not issue short-horizon forecasts. Standard errors are reported in parentheses below coefficients.
All other variables are defined in the notes to Table 2.

Variable Definitions:
Ln(*NEWS_RATIO*) = natural logarithm of *NEWS_RATIO*;
NEWS_RATIO = 100 ∗ *ABS*(*EAR*)/*ABS*(*NEAR*);
ABS(*EAR*) = absolute value of cumulative market-adjusted returns on trading days −1 to +1 relative to the QEA date;
ABS(*NEAR*) = absolute value of the cumulative market-adjusted non-earnings-announcement period returns;
BNEWS = an indicator variable equal to 1 if overall quarterly return *RET* is negative, and 0 otherwise;
RInfoAsymm = decile rank of *InfoAsymm*, which is extracted from a principal-components analysis, and is negatively associated with firm size, analyst following, and institutional ownership, and positively associated with idiosyncratic volatility and the adverse selection component of the bid-ask spread;
RBTM = decile rank of beginning-of-period book-to-market; and
RLEV = decile rank of beginning-of-period financial leverage.

just that including the QEA. Therefore, we control for *BIAS_ADJ*, which is defined as the natural logarithm of the ratio of news released during a random three-day window in the quarter relative to that released during the period in that quarter outside the window.[20]

Equation (2) expands the set of control variables to capture systematic differences in earnings informativeness arising from firm characteristics. *RInfoAsymm* is the decile rank of *InfoAsymm* within every quarter. Greater information asymmetry between managers and shareholders, and the general uncertainty typically characterizing high-information-asymmetry firms, can significantly influence earnings informativeness relative to other sources. For example, Bamber (1987) and McNichols (1988) argue that the role of earnings in conveying information varies with the information environment of the firm, which they capture empirically with firm size.

Given that managers often possess private information, their voluntary disclosures, as well as their financial reporting choices, are likely influenced by their own trading patterns (Noe 1999). Consequently, we control for the effect of *INSALE* on the informativeness of earnings. We control for *TRADE_DAYS*, since longer quarters can allow managers more time to disclose news before the actual earnings announcement and, thus, reduce earnings informativeness.

The nature of the investment opportunity set—in particular, the extent to which it is driven by growth options—can influence the information content of earnings (Collins and Kothari 1989). We control for the investment opportunity set using *RBTM*, the decile rank of the book-to-market ratio, and membership in a technology-intensive industry, denoted *HITECH*. Finally, additional scrutiny of earnings information by debt-holders can influence earnings informativeness; since such scrutiny is likely to be increasing in leverage, we control for *RLEV*, the decile rank of financial leverage.

---

[20] Differencing *Ln*(*NEWS_RATIO*) and *BIAS_ADJ* to construct a dependent variable adjusted for bias is problematic. Each term in the difference would be a logged ratio, and differencing would yield the logarithm of a ratio of two ratios, very difficult to interpret economically.

Model 1 in Panel B of Table 3 reports the results of estimating Equation (1) over the entire sample of 152,275 firm-quarters. Models 2 through 4 impose controls for firm characteristics (Equation (2)). In Models 1 through 3, the dependent variable is our primary ratio, *Ln*(*NEWS_RATIO*), and in Model 4, it is the decile rank of *NEWS_RATIO*, along with a decile rank of *BIAS_ADJ* as the control. All models are estimated on the pooled sample using ordinary least squares methodology. Standard errors are clustered by firm and fiscal year-quarter in Models 1, 2, and 4. In Model 3, we include firm fixed effects and cluster standard errors by fiscal year-quarter.

In all four models presented in Table 3, Panel B, the coefficient on *BNEWS* is positive and statistically significant at the 1 percent level. To estimate the economic effect of *BNEWS*, we first compute the implied *NEWS_RATIO* for good-news quarters by setting all control variables except *BIAS_ADJ* to their mean values, and *BNEWS* equal to 0. *BIAS_ADJ* is also set equal to 0, to prevent it from inducing a mechanical bias into our estimate of earnings informativeness. This yields an implied *NEWS_RATIO* of approximately 16.0 percent for good-news quarters in Models 1, 2, and 3, indicating that in good-news quarters, news released during earnings announcements is around 16 percent of net news released during the non-announcement period. Subsequently, we follow a similar procedure to estimate the implied *NEWS_RATIO* for bad-news quarters by setting *BNEWS* equal to 1. The implied *NEWS_RATIO* indicates that in bad-news quarters, news released during earnings announcements is around 18 percent of net news released during the non-announcement period. Consistent with H1, the results further imply that during bad-news quarters, earnings informativeness is 12.0 percent higher than during good-news quarters.

We expect earnings informativeness in bad-news quarters relative to good-news quarters to be more pronounced in the sample of firms without short-horizon forecasts; that is, forecasts of current quarter's earnings issued after the previous quarter's earnings announcements. First Call's coverage on management forecasts has substantially expanded since 1995 (see Anilowski et al. 2007). Therefore, we investigate the difference between firms with and without short-horizon forecasts within the subsample of 134,658 firm-quarters between 1995 and 2006, and report the results in Table 3, Panel C. First, in Model 1, we provide the results of Equation (2) reestimated on the subsample of all firm-quarters between 1995 and 2006. Models 2 and 3 of Table 3, Panel C, include the subsamples of firm-quarters with and without forecasts, respectively, starting in 1995.

In untabulated analyses, we observe that mean (median) quarterly returns (*RET*) for firms issuing short-horizon forecasts are around −5.2 percent (−5.5 percent), while mean (median) quarterly returns for firms not issuing short-horizon forecasts are around 2.3 percent (0.02 percent). Focusing on firms experiencing bad news ($RET < 0$), mean (median) returns for bad-news firm-quarters with short-horizon forecasts are around −22.0 percent (−18.0 percent), while mean (median) quarterly returns for bad-news firm-quarters without short-horizon forecasts are around −16.3 percent (−12.2 percent).[21] Thus, the return data suggest that managers issue short-horizon forecasts in quarters in which the news reaching the market is particularly negative, and litigation risk is presumably more pronounced (Francis et al. 1994; Skinner 1997).

---

[21] All reported differences in *RET* between firms with short-horizon forecasts and those without such forecasts are statistically significant at the 1 percent level, using t-statistics with standard errors clustered by firm and year-quarter for the means and Z-statistics from the Wilcoxon rank-sum test for the medians. These results are untabulated.

Model 2 presents results for 14,152 firm-quarters between 1995 and 2006 with short-horizon forecasts.[22] We find that for this subsample, earnings are *less* informative in bad-news quarters than in good-news quarters. The coefficients imply that the ratio of news disclosed during QEAs to that disclosed during non-QEA periods is 12.6 percent in bad-news quarters, as opposed to 13.8 percent in good-news quarters. The results are consistent with short-horizon forecasts preempting bad news at the earnings announcements.

For the 120,506 firm-quarters between 1995 and 2006 *without* short-horizon forecasts, Model 3 indicates strong support for H1. After imposing various controls, the coefficient on *BNEWS* in Model 3 is positive and statistically significant at the 1 percent level. The implied *NEWS_RATIO* for the average firm is 18.9 percent in bad-news quarters and 16.3 percent in good-news quarters. The difference of 2.6 percent points implies that earnings are around 16.0 percent (or 2.6/16.3) more informative during bad-news quarters relative to good-news quarters. Recall that by selection, in the sample of firms without any short-horizon forecasts, litigation risk is not high enough to warrant early public disclosure of impending bad news.

Collectively, the evidence suggests that the prospect of earnings eventually revealing withheld bad news induces managers to preemptively disclose information that is particularly negative, and is, thus, presumably associated with higher litigation risk. In the remaining majority of cases, when the magnitude of bad news is relatively low, it is earnings rather than preemptive short-horizon disclosures that reveal the bad news.[23]

Cross-Sectional Variation in Earnings' Informativeness

We test the cross-sectional variation in earnings' more pronounced role in disclosing bad news relative to good news using the following regression:

$$\begin{aligned} Ln(NEWS\_RATIO_t) = {} & \alpha_0 + \alpha_1{*}BIAS\_ADJ_t + \alpha_2{*}RInfoAsymm_{t-1} + \alpha_3{*}INSALE_t \\ & + \alpha_4{*}TRADE\_DAYS_t + \alpha_5{*}RBTM_{t-1} + \alpha_6{*}RLEV_{t-1} \\ & + \alpha_7{*}HITECH_{t-1} + \beta_0{*}BNEWS_t + \beta_1{*}BIAS\_ADJ_t{*}BNEWS_t \\ & + \beta_2{*}RInfoAsymm_{t-1}{*}BNEWS_t + \beta_3{*}INSALE_t{*}BNEWS_t \\ & + \beta_4{*}TRADE\_DAYS_t{*}BNEWS_t + \beta_5{*}RBTM_{t-1}{*}BNEWS_t \\ & + \beta_6{*}RLEV_{t-1}{*}BNEWS_t + \beta_7{*}HITECH_{t-1}{*}BNEWS_t + \varepsilon_t. \end{aligned} \tag{3}$$

Equation (3) is similar to Equation (2), except that it introduces partitioning variables and allows the intercept and the coefficient on *BNEWS* to vary with the partitioning variables via the interaction terms.

---

[22] The proportion of firm-quarters with short-horizon forecasts in our sample is relatively low. Even after the passage of Regulation Fair Disclosure, firm-quarters with short-horizon forecasts constitute only 11 percent of our sample (20 percent value-weighted). Note that this is much lower than the proportion of firm-quarters in our sample that report negative quarterly returns (47 percent, 48 percent value-weighted) or even negative earnings announcement returns (50 percent, 47 percent value-weighted), indicating that a relatively large proportion of firms do *not* preempt bad news.

[23] In additional analysis, we further partition the sample of firms that issue short-horizon earnings forecasts into firm-quarters with management forecasts that convey negative information versus those that convey positive information. As expected, in the sample of firm-quarters with management forecasts conveying negative information, earnings' informativeness in bad-new quarters is lower than that in good-news quarters. However, there is significant evidence of earnings' greater informativeness in bad-news quarters in the sample of firm-quarters with management forecasts conveying positive information. These findings indicate that when negative information is not disclosed in voluntary disclosures, it is released by earnings.

RInfoAsymm $*$ *BNEWS* is included as an explanatory variable to test whether earnings' differential informativeness during bad news periods is higher among firm-quarters characterized by greater information asymmetry (H2). *INSALE* $*$ *BNEWS* tests whether earnings' differential informativeness is higher among firm-quarters including insider sale of stock (H3). Finding significant and positive β_2 and β_3 would, therefore, provide support for H2 and H3, respectively. We also include *TRADE_DAYS*, *RBTM*, *RLEV*, *HITECH*, and *BIAS_ADJ* independently and interacted with *BNEWS* as control variables.

Table 4, Model 1, presents results on cross-sectional variation for the full sample using our main specification. The coefficient on *RInfoAsymm* in Model 1 is significantly negative, implying that earnings informativeness in good-news quarters is declining with our measure of information asymmetry. More importantly, consistent with H2, the coefficient on *RInfoAsymm* $*$ *BNEWS* is significantly positive at the 1 percent level, indicating that earnings *differential* informativeness in bad-news quarters, relative to good-news quarters, is increasing in the degree of information asymmetry. Moreover, consistent with H3, earnings' differential informativeness in bad-news quarters, relative to good-news quarters, is higher when there is net selling of the firm's stock by insiders during the quarter (the coefficient on *INSALE* $*$ *BNEWS* is 0.133, and significant at the 1 percent level). We draw similar conclusions from Model 2 with firm fixed effects. In Model 3, we use decile ranks of *NEWS_RATIO* as the dependent variable, and replace *BIAS_ADJ* with decile ranks of the variable, as well. We note that the coefficients on both variables of interest (*RInfoAsymm* $*$ *BNEWS* and *INSALE* $*$ *BNEWS*) are of the predicted signs and statistically significant at the 1 percent level.

To evaluate the economic magnitude of earnings' differential informativeness for firms with varying levels of information asymmetry and with or without net insider sales, we compute implied ratios based on the coefficients obtained from Model 1, and present the ratios in Panel B of Table 4. We first estimate base case implied ratios, in which we set *RInfoAsymm*, *INSALE*, and *BIAS_ADJ* to 0 and all other explanatory variables to their mean values. The implied *NEWS_RATIO* for firms in the lowest rank of information asymmetry and no net insider sales is 19.7 percent in bad-news quarters, while it is 18.2 percent in good-news quarters. Thus, earnings are 1.5 percent points, or 8.6 percent, more informative in bad-news quarters than in good-news quarters for firms with low information asymmetry and no net insider sales. For firms in the highest rank of information asymmetry (but with no net insider sales), the implied *NEWS_RATIO* is 17.0 percent in bad-news quarters, and 12.3 percent in good news quarters, implying that earnings are 4.7 percent points, or 37.8 percent, more informative in bad-news quarters than in good-news quarters. Differential informativeness of earnings also increases relative to the base case for firms with net insider sales. The implied *NEWS_RATIO* for firms with net insider sales (but in the lowest rank of information asymmetry) is 22.6 percent in bad-news quarters, and 18.3 percent in good-news quarters, implying that earnings are 4.3 percent points, or 23.6 percent, more informative in bad-news quarters than in good-news quarters.

V. ADDITIONAL ANALYSES

Earnings' Differential Informativeness by Fiscal Quarter

To investigate further the role of the earnings reporting process in influencing earnings' differential informativeness, we examine how the latter varies across the four fiscal quarters. In the first three fiscal quarters, auditors only review financial reports, while in the fourth quarter, they perform a complete and thorough annual audit of statements that are subsequently submitted to the Securities and Exchange Commission (SEC). If the year-end audit is primarily responsible for the

*, **, *** Represent statistical significance at a minimum 0.1, 0.05, and 0.01 levels, respectively.
Table 4, Panel A, Models 1 and 3, present the results of OLS regressions with standard errors clustered by firm and fiscal year-quarter, while Model 2 is estimated using OLS with firm fixed effects and standard errors clustered by fiscal year-quarter. The dependent variable in Models 1 and 2 is *Ln(NEWS_RATIO)*. The dependent variable in Model 3 is the decile rank of *NEWS_RATIO* (*Ranked NEWS_RATIO*). All models include the sample of 152,275 firm-quarters between 1987 and 2006. Panel B reports Implied Ratios, computed as the exponent of the predicted *Ln(NEWS_RATIO)* obtained by setting all control variables to their means except for *BIAS_ADJ*, which is set equal to 0, *BNEWS*, equal to 1 or 0, and *RInfoAsymm* and *INSALE*, which are set to the values reported in the table. Standard errors are reported in parentheses below coefficients.
All other variables are defined in the notes to Tables 1 and 2.

Variable Definitions:
Ln(NEWS_RATIO) = natural logarithm of *NEWS_RATIO*;
NEWS_RATIO = 100 ∗ *ABS(EAR)/ABS(NEAR)*;
ABS(EAR) = absolute value of cumulative market-adjusted returns on trading days −1 to +1 relative to the QEA date;
ABS(NEAR) = absolute value of the cumulative market-adjusted non-earnings-announcement period returns; and
BNEWS = an indicator variable equal to 1 if overall quarterly return *RET* is negative, and 0 otherwise.

release of bad news in earnings, then earnings' differential informativeness should be concentrated in the fourth fiscal quarter.

Table 5 presents the results of estimating earnings' differential informativeness with respect to bad news by fiscal quarter. The coefficient on *BNEWS* is statistically insignificant in the first and second fiscal quarters, and significant at the 5 percent or higher level in the third and fourth fiscal quarters. In magnitude, the coefficient on *BNEWS* at first increases across quarters, reaching its peak in the third fiscal quarter, and then exhibits a slight decline. The coefficients imply that earnings are only around 5.6 percent more informative about bad news in the first fiscal quarter, and that this effect increases to 10.5 percent in the second fiscal quarter; the corresponding percentages are around 15.1 percent for the third fiscal quarter and 13.3 percent for the fourth. Interestingly, earnings informativeness with respect to both good and bad news exhibits a lower magnitude in the fourth fiscal quarter than in the third.

One interpretation of the results is that as the year-end audit approaches, managers release more bad news via the earnings reporting process, causing the observed rise in earnings' differential informativeness over the first three fiscal quarters. However, in the fourth quarter, the imminent release of audited annual results can generate intensified scrutiny of the firm by market participants, even prior to the earnings announcements, prompting managers to provide more voluntary disclosures (Baginski and Hassell 1990). This is possibly responsible for the diminished informativeness of earnings in the fourth quarter, with respect to both bad and good news.

Table 5 presents the results from OLS regressions estimated separately for fiscal Quarters 1–4. Standard errors are clustered by firm and fiscal year-quarter. The dependent variable is *Ln*(*NEWS_RATIO*). Implied Ratio is the exponent of the predicted *Ln*(*NEWS_RATIO*), obtained by setting all control variables to their means except for *BIAS_ADJ*, which is set equal to 0, and *BNEWS*, equal to 1 or 0. Standard errors are reported in parentheses below coefficients.

All other variables are defined in the notes to Tables 1 and 2.

Variable Definitions:

Ln(*NEWS_RATIO*) = natural logarithm of *NEWS_RATIO*;
NEWS_RATIO = 100 * *ABS*(*EAR*)/*ABS*(*NEAR*);
ABS(*EAR*) = absolute value of cumulative market-adjusted returns on trading days −1 to +1 relative to the QEA date;
ABS(*NEAR*) = absolute value of the cumulative market-adjusted non-earnings-announcement period returns; and
BNEWS = an indicator variable equal to 1 if overall quarterly return *RET* is negative, and 0 otherwise.

Earnings Misses

In expanded cross-sectional analyses, we test whether earnings' differential informativeness during bad-news quarters can indeed be attributed to negative information conveyed *directly* by earnings information. The primary example of earnings conveying negative information is when realized earnings fall short of prevailing expectations at the time of the earnings announcement. We define an indicator variable, *MISS*, set equal to 1 when actual earnings fall below earnings expectations. Earnings expectations are based on consensus analyst forecasts if analyst data are available; otherwise, they are based on a seasonal random walk.[24] Our results (untabulated) reveal that earnings' differential informativeness is significantly more pronounced in quarters when earnings fall below market expectations. The finding confirms that negative earnings surprises contribute to the increased informativeness of earnings that we observe in bad-news quarters using our returns-based measure.

Subperiod Analysis

There were two significant regulatory events during our sample period that are likely to have influenced both voluntary disclosure and financial reporting practices: Regulation Fair Disclosure (REG FD), effective since the fourth calendar quarter of 2000, and the Sarbanes Oxley Act (SOX), effective since the third calendar quarter of 2002.[25] In this section, we examine earnings informativeness in three subperiods: (1) before REG FD, (2) after REG FD, but before SOX, and (3) after SOX. The passage of REG FD and SOX was associated with a period of significant turmoil in the capital markets, particularly with the reporting scandals involving audit firms such as Arthur Andersen and a large number of U.S. corporations such as WorldCom, Enron, Qualcomm, etc. These confounding events imply that any observed change in earnings informativeness cannot be exclusively attributed to REG FD and/or SOX, and in that sense, our evidence is descriptive. Nevertheless, it is instructive to learn how earnings informativeness varied across this turbulent period, within which the passage of REG FD and SOX represent two clearly identifiable watershed events.

Table 6 reports the results of subperiod analyses testing for changes in the differential informativeness of earnings announcements with respect to bad news versus good news with the passage of REG FD and SOX. Consequently, we examine three subperiods in our sample. Model 1 of Table 6 includes the first subperiod: all fiscal quarters which, in calendar time, precede the fourth quarter of 2000 (PRE-REG-FD). Model 2 includes the second subperiod: all fiscal quarters which, in calendar time, correspond to or follow the fourth quarter of 2000, and precede the third quarter of 2002 (POST-REG-FD PRE-SOX). Model 3 includes the third subperiod: all remaining fiscal quarters which, in calendar time, correspond to, or follow, the third quarter of 2002 (POST-SOX). We find that the coefficient on *BNEWS* is not statistically significant in the PRE-REG-FD period, but positive and significant at the 1 percent level in the more recent POST-REG-FD and POST-SOX periods.

As reported in Panel B in Table 6, the implied *NEWS_RATIO* in the PRE-REG-FD subperiod for a firm with average values of the control variables is 15.2 percent in bad-news quarters, and 14.8 percent in good-news quarters; this small difference is not statistically significant at conventional levels. Interestingly, in the second subperiod, the implied *NEWS_RATIO* for bad-news quarters rises to 19.3 percent, while for good-news quarters, it decreases marginally to 13.2 percent. The increase in the implied *NEWS_RATIO* from the previous subperiod is significant at the 5 percent level for bad-news quarters. The results suggest that the changes in the information environment

---

[24] The consensus analyst forecast is the mean across the final forecast provided by each analyst in a given announcement quarter. Using the median consensus analyst forecast yields similar results.

[25] Gintschel and Markov (2004) and Mohanram and Sunder (2006) conclude that REG FD largely succeeded in its objective of restricting selective voluntary disclosure. Further, Wang (2007) and Chen et al. (2011) document evidence suggesting that REG FD adversely affected the informativeness of voluntary disclosures. With respect to SOX, Cohen et al. (2007) document evidence consistent with firms having less flexibility in reporting earnings-increasing discretionary accruals in the post-SOX period.

, * Represent statistical significance at a minimum 0.05 and 0.01 levels, respectively.

Table 6, Panel A, presents the results of OLS regressions with standard errors clustered by firm and fiscal year-quarter. The dependent variable is *Ln*(*NEWS_RATIO*). Model 1 includes all fiscal quarters which, in calendar time, precede the enactment of Regulation FD in the fourth quarter of 2000 (PRE-REG-FD). Model 2 includes all fiscal quarters which, in calendar time, correspond to, or follow, the fourth quarter of 2000, and precede the enactment of the Sarbanes-Oxley Act in the third quarter of 2002 (POST-REG-FD PRE-SOX). Model 3 includes all remaining fiscal quarters which, in calendar time, correspond to, or follow, the third quarter of 2002 (POST-SOX). Standard errors are reported in parentheses below coefficients. Panel B presents Implied Ratios, which are computed as the exponent of the predicted *Ln*(*NEWS_RATIO*) obtained by setting all control variables to their means except for *BIAS_ADJ*, which is set equal to 0, and *BNEWS*, equal to 1 or 0.

(continued on next page)

TABLE 6 (continued)

All other variables are defined in the notes to Tables 1 and 2.

Variable Definitions:
Ln(*NEWS_RATIO*) = natural logarithm of *NEWS_RATIO*;
NEWS_RATIO = 100 * *ABS*(*EAR*)/*ABS*(*NEAR*);
ABS(*EAR*) = absolute value of cumulative market-adjusted returns on trading days −1 to +1 relative to the QEA date;
ABS(*NEAR*) = absolute value of the cumulative market-adjusted non-earnings-announcement period returns; and
BNEWS = an indicator variable equal to 1 if *RET* is negative, and 0 otherwise.

around the passage of REG FD made earnings' role in conveying bad news more pronounced POST-REG FD.

Finally, Model 3 indicates that in the POST-SOX subperiod, the implied *NEWS_RATIO* for bad-news quarters is 22.9 percent, significantly higher than in the previous subperiod. The implied *NEWS_RATIO* for good-news quarters increases more sharply to 19.8 percent (relative to 13.2 percent in the second subperiod); this increase is statistically significant at the 1 percent level. The evidence suggests that SOX, along with the events surrounding its passage, enhanced the role of earnings in conveying both good and bad news, but that this effect was stronger with respect to good news.[26] The net effect is a decline in earnings' differential informativeness in bad-news quarters relative to good-news quarters in the POST-SOX period. Importantly, however, the differential informativeness of earnings remains significant in the POST-SOX period.

Management Forecasts Issued along with QEAs

In robustness analyses, we identify those firm-quarters in which QEAs are accompanied by management forecasts of earnings. For these observations, it is not possible to distinguish the part of the information released during the three-day QEA window that is attributable to the current quarter's earnings information from that attributable to the accompanying voluntary disclosure. Consequently, we reestimate our regressions after excluding these observations. The excluded observations constitute around 14.0 percent of the overall sample, and become increasingly prevalent with time. They constitute only 2.6 percent of the sample PRE-REG-FD, around 20.4 percent of the sample in the POST-REG-FD PRE-SOX subperiod, and around 29.0 percent of the sample in the POST-SOX subperiod. Our results on the primary hypothesis and cross-sectional variation are robust to the exclusion of observations in which QEAs are accompanied by management forecasts. Moreover, the general time-series patterns observed in Table 6 are robust to the exclusion, as well. Implied *NEWS_RATIO*s for the restricted sample during bad-news and good-news quarters are, respectively, 14.2 percent and 14.4 percent in the PRE-REG-FD subperiod, 17.8 percent and 12.5 percent in the POST-REG-FD PRE-SOX subperiod, and 20.3 percent and 17.1 percent in the POST-SOX subperiod.

VI. CONCLUSION

The collective evidence in our paper suggests that earnings play a valuable information role by mitigating delays in bad-news disclosures in the large majority of cases when litigation risk is not high enough to warrant preemptive voluntary disclosures. Using returns-based measures to capture news, we find that the ratio of news released during the three days around the QEA date to that released during the non-QEA period is significantly greater when quarterly returns are negative, relative to when they are positive. As expected, our evidence is concentrated among firms that do not issue short-horizon forecasts.

---

[26] Consistent with our findings, Ball and Shivakumar (2008) also note the general increase in QEA informativeness with time (particularly post-SOX), although they do not condition on the sign of overall news.

Our cross-sectional tests provide evidence that earnings increased informativeness during bad-news quarters is even greater in firms characterized by higher information asymmetry between managers and shareholders, and in firm-quarters with net insider sales of stock. We also analyze whether earnings' differential informativeness varies by fiscal quarter and in time-series. We find that earnings' differential informativeness is concentrated in the third and the fourth fiscal quarters. Subperiod analysis indicates that earnings' informativeness in bad-news quarters, relative to good-news quarters, becomes more pronounced in the later part of our sample period, particularly after the passage of Regulation Fair Disclosure, and persists in the post-SOX period.

Our paper contributes to the existing literature by providing evidence that earnings information plays a crucial role in limiting delays in the release of bad news to the market. Direct evidence on the news earnings convey is particularly critical at this point in time, as the Financial Accounting Standards Board (FASB) considers new standards, presumably for the purpose of making earnings more informative (Johnson 2005; FASB 2007; Kothari et al. 2010). Our findings indicate that the standard-setters, in drafting the new standards, need to bear in mind that earnings' value as an information source may lie in the *ex post* settling-up role that they play with respect to negative information. In certain cases, as when litigation risk is high, the prospect of releasing negative news at the earnings announcements can prompt managers to disclose such news voluntarily in a timely manner. When factors such as litigation risk are not high enough to induce voluntary disclosures, and managers' incentives to delay bad news disclosures are more pronounced, earnings release the negative information that has not reached the market via alternative sources.

APPENDIX A

NEWS_RATIO MAGNITUDES UNDER VARIOUS SCENARIOS

	***EAR, NEAR* of the Same Sign**		***EAR, NEAR* of Different Sign**	
	$EAR < 0$ $NEAR < 0$	$EAR > 0$ $NEAR > 0$	$EAR > 0$ $NEAR < 0$	$EAR < 0$ $NEAR > 0$
$RET < 0$				
Consistency with H1	Could be consistent or inconsistent	Not possible	Inconsistent	Consistent
Magnitude of *NEWS_RATIO*	High if consistent, Low if not	Not possible	Low	High
$RET \geq 0$				
Consistency with H1	Not possible	Could be consistent or inconsistent	Inconsistent	Consistent
Magnitude of *NEWS_RATIO*	Not possible	Low if consistent, High if not	High	Low

This appendix tabulates the scenarios under which *NEWS_RATIO* is expected to be relatively high versus relatively low. *NEWS_RATIO* is defined as 100 * *ABS(EAR)/ABS(NEAR)*. *EAR* is the cumulative market-adjusted returns on trading days −1 to +1 relative to the quarterly earnings announcement (QEA) date, *NEAR* represents the cumulative market-adjusted non-QEA period returns (spanning all trading days included in *RET* except for the trading days included in *EAR*). *ABS*(*EAR*) and *ABS*(*NEAR*) represent absolute values for *EAR* and *NEAR*, respectively. *RET* represents quarterly market-adjusted returns beginning two days after the QEA date for the previous quarter and ending one day after the QEA date for the current quarter.

To establish the patterns in *NEWS_RATIO*, first consider cases when *EAR* and *NEAR* are of the same sign. If it is true that earnings play a proportionately greater role in releasing bad news than good news, as our hypothesis states, then for cases when $RET < 0$, *ABS*(*EAR*) is expected to be high relative to *ABS*(*NEAR*). Similarly, when $RET > 0$, our hypothesis would imply that *ABS*(*EAR*) is expected to be low relative to *ABS*(*NEAR*).

Next, consider the scenarios with differing signs on *EAR* and *NEAR*, beginning with the case when $RET < 0$, $EAR < 0$, and $NEAR > 0$. This case is clearly consistent with our hypothesis: all of the negative information is released at the *QEA*s. Since overall returns are negative, by construction, *EAR* will be higher than *NEAR* in magnitude and *NEWS_RATIO* will be high. The scenario where $RET < 0$, $EAR > 0$, and $NEAR < 0$ is inconsistent with our hypothesis: all of the negative information is released during the non-QEA period. *EAR*, by construction, must be lower in magnitude than *NEAR*, since overall returns are negative, generating a low *NEWS_RATIO*. Thus, *NEWS_RATIO* functions well as an empirical proxy by assuming high values for negative-return observations, consistent with our hypothesis, and lower values for those that are inconsistent.

To generate the asymmetry predicted by our hypothesis, *NEWS_RATIO* also needs to assume lower values for all positive-*RET* observations that are consistent with our hypothesis, and higher values for those that are inconsistent. We examine the positive-*RET* cases with *EAR* and *NEAR* of differing signs to ensure that this is true. First, we focus on $RET > 0$, $EAR < 0$, and $NEAR > 0$. This case is consistent with our hypothesis: all of the positive information for the period reaches the market during the *non-QEA* period. Since overall returns are positive, by construction, *EAR* will be lower than *NEAR* in magnitude, and *NEWS_RATIO* will be low. Finally, in the positive-return case that is inconsistent with our hypothesis ($RET > 0$, $EAR > 0$, and $NEAR < 0$), *EAR*, by construction, has to be higher in magnitude than *NEAR*, since overall returns are positive, generating a higher *NEWS_RATIO*. In summary, variation in *NEWS_RATIO* is well suited to testing whether the relative informativeness of earnings is higher when overall information reaching the market is negative.

Consecutive Earnings Surprises: Small and Large Trader Reactions

Devin M. Shanthikumar
University of California, Irvine

ABSTRACT: Prior research demonstrates that investors respond differently to earnings surprises that are part of a string of consecutive earnings increases or surprises than to those that are not. To shed light on who values these patterns, I compare trading responses of small and large traders to earnings surprises that occur during a series of positive or negative surprises. I find that the relative intensity of small traders' trading response (and, to a lesser extent, that of medium traders) to earnings surprises generally increases as a series progresses. Small traders respond more negatively to the second (third) negative surprise in a series than to the first (second), and more positively for the first three surprises in a positive series. Moreover, I find that announcement-period returns are related to the trading of small and medium traders. These results suggest that less sophisticated smaller traders, responding to earnings series, contribute to previously documented pricing patterns.

Keywords: *earnings string; earnings pattern; earnings momentum; trade imbalance; small and large trade.*

Data Availability: *All data used in this study, with the exception of data obtained from an anonymous discount brokerage firm, are publicly available from the sources indicated in the text.*

I. INTRODUCTION

Prior research indicates that investors respond more strongly to earnings surprises that occur as part of a consistent series than to surprises that do not, but provides no evidence on which investors value these earnings patterns. In particular, Barth et al. (1999) find higher

price-earnings multiples later in a "string" of consecutively increasing earnings. This paper compares the trading responses of investors who make large trades (large traders), whom research has shown to be sophisticated, and investors who make small trades (small traders), whom research has shown to be relatively naïve, to a similar pattern of earnings surprises that occur during a series of either positive or negative surprises. Since the two classes of investors differ in sophistication, differences in their response also sheds light on whether mispricing or risk drive the pricing patterns.

Following prior literature, I measure investor reactions using New York Stock Exchange Trade and Quote (TAQ) data, splitting trades into categories based on the dollar value of the trade. I classify the sign (buy versus sell) of the trades using the Lee-Ready algorithm (Lee and Ready 1991; Lee and Radhakrishna 2000; Odders-White 2000). This study examines each trade group's reaction to a "series" of consecutive "strong positive" and "strong negative" surprises, defined as the top 30 percent and bottom 30 percent of standardized unexpected earnings, respectively. If small traders exhibit a stronger reaction to consistent earnings patterns than large traders, then we should observe their relative trading response becoming more negative (positive) for a series of negative (positive) surprises.

The results show that small traders' reaction relative to large traders becomes more negative over a series of negative surprises, i.e., for the second surprise versus the first and the third versus the second. While the relative reaction becomes insignificantly less negative for the fourth or later surprises compared to the third, the relative reaction remains significantly more negative than the reaction to the first surprise. Similarly, results show that small traders' relative trade reaction becomes generally more positive for a series of positive surprises, although with an insignificant drop for fourth-and-later surprises. Small traders' relative reaction is significantly more positive for the third positive surprise than for the first or second, and for the fourth-and-later than for the first. I find similar results when comparing medium traders with large traders. In contrast, large traders react similarly to surprises in a series even when earnings surprises are defined using analyst forecasts, which proxy more strongly for large traders' expectations (Bhattacharya 2001; Battalio and Mendenhall 2005), suggesting that the relative-reaction patterns are not due to different earnings expectations of small, medium, and large traders. In contrast to trading during a series, small and large trader reactions to breaks in a series do not differ systematically with the length of the preceding series. Finally, additional analyses verify that small and medium trade imbalances are positively associated with concurrent returns around earnings announcements, even after controlling for large trades and the earnings surprise. These results provide evidence that smaller traders have a preference for consistent performance, as measured by an earnings surprise series, relative to large traders. The results are consistent with "earnings momentum" trading by small and medium traders being one driver of the return patterns documented in prior literature, at least for the first several surprises in a series.

This study contributes to the literature by providing evidence of which traders react positively to a series of consistent earnings surprises. Bhattacharya (2001) and Battalio and Mendenhall (2005) increase our understanding of post-earnings-announcement drift by showing that small traders respond most strongly to random-walk-based earnings surprises. This study increases our understanding of the market reactions to the time-series-pattern in earnings by building on that literature. Prior work that examines market responses to earnings patterns has focused on price- and returns-based tests (e.g., Barth et al. 1999; Kasznik and McNichols 2002; Myers et al. 2007). The present study's examination of the trading patterns of small and large traders has the advantage of assessing how different investors respond to the same announcement. This research design complements prior studies, providing evidence that "earnings-momentum" trading is stronger among smaller, less sophisticated investors.

One drawback to examining small and large trades is that the method is unlikely to be accurate after about 2002, as discussed in more detail in the "Data and Research Design" section. Therefore, I cannot say for certain that the results documented in this paper would extend to recent years. However, the ten-year sample period examined sheds significant light on the basic question of which investors react more strongly to a series of consistent earnings surprises.

The paper proceeds as follows. Section II describes the hypothesis development and related literature. Section III explains the empirical methods and data. Section IV presents the primary results and Section V presents additional analyses. Section VI concludes.

II. HYPOTHESIS DEVELOPMENT

Barth et al. (1999), Kasznik and McNichols (2002), Myers et al. (2007), and Lev et al. (2008) examine pricing multiples and stock returns related to patterns of consistent earnings increases or consistently positive earnings surprises, while Frieder (2008) investigates aggregate trade imbalances. All of these papers suggest that the market values consistent earnings patterns.

However, it is not clear what drives the market premium for consistency. Barth et al. (1999) suggest several possible explanations, which fall into two primary categories: (1) consistent earnings patterns may capture dimensions of growth or risk that the usual proxies for these variables do not capture, or (2) there may be an element of mispricing due to "earnings momentum" trading. Intuitively, an investor is engaged in earnings momentum trading if he/she buys (sells) stocks with positive (negative) earnings "momentum," i.e., multiple consecutive periods of positive (negative) earnings results. These two explanations lead to different predictions for investor trading, as described below.

Small and large traders are likely to differ in sophistication. First, investors making larger trades will invest more in acquiring information as fixed costs are employed to earn a larger dollar return. Conversely, an investor with better information will make a larger trade to exploit that information. Easley and O'Hara (1987) develop a theoretical model predicting that larger trades will incorporate more information and Hasbrouck (1988, 1991) provides empirical evidence consistent with this. Second, large trades tend to be made by institutional investors (Lee and Radhakrishna 2000). Experimental researchers have found that professionals are more successful in avoiding behavioral biases than nonprofessionals in several accounting and finance contexts (Smith and Kida 1991; Frederickson and Miller 2004). Finally, a growing body of empirical work finds that small traders make less sophisticated trading decisions than large traders. Bhattacharya (2001), Battalio and Mendenhall (2005), Lee (1992), and Hirshleifer et al. (2008) find that small traders buy stock following earnings announcements even if the earnings surprise is negative. Bhattacharya (2001) and Battalio and Mendenhall (2005) find that small traders rely more on a seasonal random-walk model to form their earnings expectations, even though analyst expectations impound more information. Odean (1999) and Barber and Odean (2000) show that discount brokerage account investors fail to earn returns to compensate for transaction costs and buy stocks that perform more poorly than the ones they sell. Bhattacharya et al. (2007) find differences between small and large trading around pro forma earnings announcements. Malmendier and Shanthikumar (2007, 2009), using the same trade data as this paper, and Mikhail et al. (2007) find that small investors react more naively to analyst recommendations and earnings forecasts than large traders. In all of these settings, small traders appear to make less sophisticated trading decisions than large traders. Turning to the effect of earnings series, if "earnings momentum" trading, based on behavioral factors, is a driver of the previously documented price patterns, then small, less sophisticated traders are likely to exhibit stronger earnings momentum trading than large traders.

While small and large traders appear to differ systematically in sophistication, they do not seem to differ systematically in their risk preferences. As Lee (1992) discusses, individuals have larger holdings in not only certain high-risk stocks, such as small firms and over-the-counter stocks, but also certain low-risk stocks such as utilities (Lee et al. 1991). Barsky et al. (1997) elicit risk preferences from 11,000 respondents and find no systematic relation between risk preferences and wealth or education. Brunnermeier and Nagel (2008) find that the share of households' liquid assets in risky assets does not vary with changes in wealth, suggesting that individuals' risk aversion remains steady as wealth changes. Finally, it is not clear how the risk aversion displayed by mutual fund managers compares to that of individuals. Prior literature has shown that for mutual funds, incentive fees increase risk-taking by losers but decrease risk-taking by winners (Elton et al. 2003). Absent a systematic difference in risk preferences between small and large traders, if the price patterns for earnings series are due to growth or risk, then we would expect large traders to react at least as strongly as small traders, in contrast to the prediction for "earnings momentum" trading.[1]

Examining small and large trades provides direct information on who responds to patterns of consistent earnings performance. Because small and large investors exhibit different levels of sophistication but similar risk preferences, it also provides insight on whether the pricing patterns are related to earnings momentum trading or firm risk. I state the hypothesis predicted by earnings-momentum trading as follows:

> **H1:** Small traders' net buying (selling) increases as a series of positive (negative) earnings surprises continues, relative to large traders.[2]

Section III discusses the empirical design in more detail. However one important issue is how to define an earnings "series." Barth et al. (1999) and Myers et al. (2007) focus on "strings" of five years of increasing annual and quarterly earnings, respectively. However, these definitions provide only 292 annual and 113 quarterly earnings strings for the sample for which I have trade data. In addition, small and large investors may view small earnings increases differently, making it difficult to attribute a difference in small and large trading to preferences for earnings momentum or differences in earnings expectations. For example, if results show that small traders react more strongly to a string of earnings increases than large traders, then it could be that both groups prefer "consistency" but only small traders view a 1 cent increase as good news. In contrast, strong earnings surprises are likely to be viewed as surprises by *both* investor groups. Thus, I define a "series" as a pattern of one to at least four consecutive quarters of strongly positive (top 30 percent), or negative (bottom 30 percent), earnings surprises. Because this definition of a "series" differs from corresponding definitions used in prior literature, I replicate the primary analysis in Barth et al. (1999) as a first step.

I conduct additional analyses as well. First, I test the relation between small trades and concurrent returns around earnings announcements to verify that small trades could potentially affect returns. Second, I examine trading after a break in a series. Finally, I conduct various robustness checks.

III. DATA AND RESEARCH DESIGN

The sample covers common stock for U.S. firms on the New York Stock Exchange (NYSE) between 1993 and 2002, including 2,723 firms and 59,658 earnings announcements. I take returns from CRSP, earnings data and firm characteristics from Compustat, analyst earnings forecasts from the Institutional Brokers Estimates System (I/B/E/S), and trade and quote data from the NYSE Trade and Quote (TAQ) database.

---

[1] To see why sophisticated investors will react at least as strongly as unsophisticated investors if returns are due to changes in risk or growth, consider two possibilities for price-adjustment. First, consider the case where prices adjust immediately to the change in risk signaled by the earnings pattern. In this case, both groups hold stocks that are priced correctly, so we would not expect any differential reaction. Second, consider the case where there is some friction in price-adjustment and prices do not adjust immediately. By reacting (buying or selling), sophisticated investors can earn abnormal returns until prices reach equilibrium levels, so we would expect more sophisticated investors to react more strongly.

[2] The predictions for small and large traders are relative predictions. It may be the case that even large traders "prefer consistency." However, I argue that if the preference for consistency is based on behavioral factors, then small traders will exhibit a *stronger* preference. Since it is almost impossible to determine the correct trade response, I use large traders as the benchmark.

Measuring Earnings Surprise Events

I define the event date using the quarterly earnings announcement date from Compustat. The main measure of earnings surprise is standardized unexpected earnings, which adjusts for expectations without restricting the sample to firms with analyst coverage. This is important as large trades might dominate the generally larger and higher institutional-ownership firms that have analyst coverage. To calculate standardized unexpected earnings (SUE), I estimate the model used in Foster et al. (1984) and Bernard and Thomas (1989) and assume that earnings expectations are based on a seasonal random-walk with drift. The model defines expected earnings as:

$$E(e_t^i) = e_{t-4}^i + \delta^i, \tag{1}$$

where δ^i is the earnings drift for firm i. For each stock, I estimate drift as:

$$\hat{\delta}^i = (1/n)\sum_{j=1}^{n}(e_{t-j}^i - e_{t-j-4}^i), \tag{2}$$

where $n \leq 16$. Unexpected earnings are then standardized by the standard deviation of earnings, as measured by the available subset of the preceding 20 announcements. Thus:

$$SUE_t^i = \frac{e_t^i - e_{t-4}^i - \hat{\delta}^i}{\sqrt{Var(e_t^i)}}. \tag{3}$$

Finally, earnings announcements are ranked by SUE within each year.[3]

I use analyst forecasts to define an alternative measure of earnings surprises. The surprise is the difference between announced earnings-per-share and the most recent monthly median forecast before the announcement, normalized by stock price as of the forecast consensus date, when there are at least four earnings forecasts for the firm. Using this measure reduces the sample to 29,649 earnings announcements.

Defining the Earnings Surprise Series

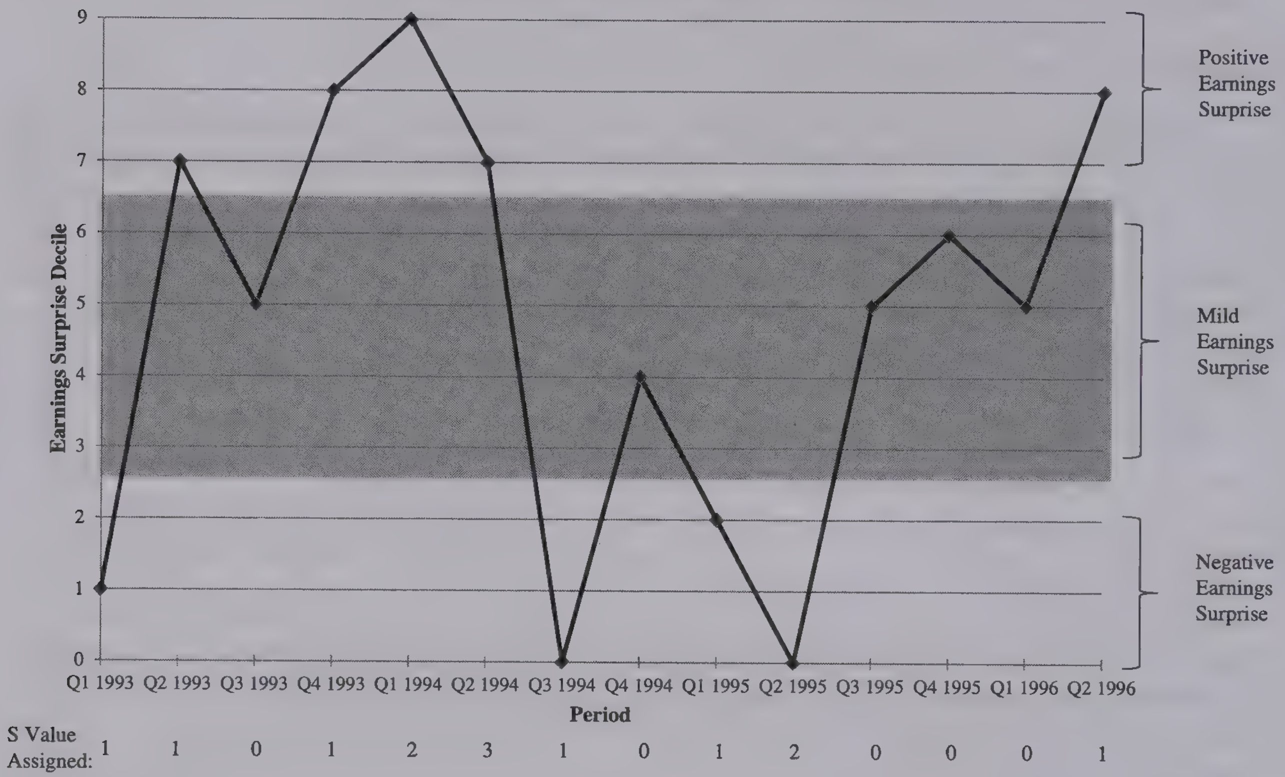
I denote the position of a given surprise in an earnings surprise series by S. For a given surprise, S = 1 if the surprise is strongly negative (positive), i.e., in the bottom 30 percent (top 30 percent) of earnings surprises and the preceding surprise for that firm was not strongly negative (positive). S = 2 if it is the second surprise of the same type, strongly negative or positive, S = 3 if it is the third, and so on. An earnings surprise is assigned a value of S equal to 0 if it is neither a strongly negative nor strongly positive surprise, i.e., if it is in the middle 40 percent of earnings surprises. Figure 1 provides an example.

Table 1 reports sample statistics for the full sample and subsamples based on S. Between 40 percent and 60 percent of S = 1 and S = 2 surprises are followed by S = 2 and S = 3 surprises, respectively, for both positive and negative series, so that each surprise in the series is likely to be a surprise. The magnitude of standardized unexpected earnings does not vary systematically with S. Firm size and book-to-market do not vary systematically for positive earnings surprise series.

---

[3] Results are similar when I use a seasonal random-walk without drift and normalization of the unexpected earnings measure by the standard deviation of earnings changes.

FIGURE 1
Defining Earnings Surprise Series



This figure presents an example for the assignment of "S" values, where S marks how far into a series a given surprise falls. Earnings surprises are assigned to deciles (0 through 9) in each quarter, where a decile of 0, 1, or 2 indicates an earnings surprise in the most negative 30 percent, while a decile of 7, 8, or 9 indicates a surprise in the most positive 30 percent. If a surprise is the first in a series of same-type extreme surprises (bottom 30 percent, i.e., deciles 0, 1, or 2, or top 30 percent, i.e., deciles 7, 8, or 9), then it receives a value of S = 1. If it is second in a series, then S = 2 and so on. "Mild" surprises, in the middle 40 percent, i.e., deciles 3 through 6, are assigned S = 0.

However, for a negative series, firm size decreases and book-to-market increases. The change in book-to-market is driven by the decrease in market value. Book value of equity decreases with S for negative series; however, market value decreases more strongly. Given these patterns, I include size as a control variable in the analysis.

Measuring Small and Large Trading

Following Malmendier and Shanthikumar (2007), I restrict the sample to 1993–2002 common stock traded on the New York Stock Exchange (NYSE) to ensure a robust separation of small and large trades. Malmendier and Shanthikumar (2007) discuss some of the potential problems with these methods after 2002. Increased splitting of trades by institutions, internalization, program trading, and more frequent quote updating reduce the efficacy of the small/large trade distinction and the Lee-Ready algorithm.

I classify each NYSE trade from the TAQ data as buyer or seller initiated using the modified Lee and Ready (1991) algorithm recommended in Odders-White (2000). The algorithm involves matching a trade to the most recent quote preceding the trade by at least five seconds. If a price is nearer the bid (ask) price, then it is classified as seller (buyer) initiated. If a trade is at the bid-ask

This table presents sample statistics for firm-quarters for NYSE common stock from 1993 through 2002, with matching TAQ trading data for each of the 11 days surrounding the earnings announcement (i.e., trading days [−5, 5]). If a surprise is the first in a series of same-type (top or bottom 30 percent) surprises, then it receives a value of S = 1. If it is the second in a series, then S = 2 and so on. S = 0 indicates a surprise that is not in a top/bottom 30 percent series, i.e., a surprise in the middle 40 percent.

Variable Definitions:
Size = market value and is reported in millions of dollars;
B/M = (book-to-market) ratio of book value of equity to market value of equity; and
SUE = standardized unexpected earnings based on a random-walk with drift earnings expectations model.

midpoint, then it is classified using a "tick test," comparing the trade price to the price of the previous trade.[4] To separate small and large trades I use four cutoffs: \$5,000, \$10,000, \$20,000, and \$50,000.[5]

The analyses in the paper focus on "small" trades of less than \$5,000, "medium" trades between \$5,000 and \$50,000, and "large" trades of at least \$50,000, motivated by Lee and Radhakrishna (2000) who show that dollar-based cutoffs create less noise in separating individuals from institutions than share-based cutoffs and that, for their three-month sample from 1990–1991, a very low (high) cutoff such as \$5,000 (\$50,000) is most effective in separating out individuals (institutions).[6,7]

Calculating Abnormal Trading Measures

This paper focuses on abnormal trade imbalance as the primary variable of interest, calculated following the method of Malmendier and Shanthikumar (2007).[8] Intuitively, if every trade after an announcement were initiated by the buy (sell) side, then the trading reaction to that announcement is extremely positive (negative). To capture this concept, raw trade imbalance is defined as:

$$IMB_{i,x,t} = \frac{buys_{i,x,t} - sells_{i,x,t}}{buys_{i,x,t} + sells_{i,x,t}} \tag{4}$$

for firm i, investor type x, and date t. Following Malmendier and Shanthikumar (2007), I normalize raw trade imbalance by subtracting the non-event-time firm-year mean, and dividing by the standard deviation, with:

$$IMB^{abnormal}_{i,x,t} = \frac{IMB_{i,x,t} - E\left(IMB_{i,x,year(t)}\right)}{\sqrt{Var\left(IMB_{i,x,year(t)}\right)}}, \tag{5}$$

where I exclude trading days −5 through 5 around earnings announcements in calculating $E(IMB_{i,x,year(t)})$ and $Var(IMB_{i,x,year(t)})$. The normalization thus controls for systematic differences in trading behavior for different stocks, trading groups, and times, but does not correct for differences in trading reactions to earnings announcements.

---

[4] If the trade occurs at a price that is higher (lower) than the price of the previous trade, then it is classified as buyer (seller) initiated. The original Lee-Ready algorithm employs a "zero-tick" test in the case that a trade is at the bid-ask midpoint and the same price as the previous trade. Odders-White (2000) reports that the "zero-tick" misclassifies trades 40 percent of the time, and recommends leaving this 6 percent of trades unclassified. However, results are robust to using the original Lee-Ready algorithm for a large subsample of the data.

[5] The final dataset contains data from over 640 million trades, with each category containing a similar number of trades: 20.8 percent, 16.4 percent, 16.8 percent, 20.4 percent, and 25.6 percent for trades below \$5,000, between \$5,000 and \$10,000, between \$10,000 and \$20,000, between \$20,000 and \$50,000 and above \$50,000, respectively.

[6] Other papers use similar cutoffs. Lee (1992) uses a cutoff of \$10,000, with \$5,000 and \$20,000 as robustness checks. Bhattacharya (2001) uses dollar cutoffs of \$5,000 and \$50,000. Hvidkjaer (2006) uses firm-size dependent cutoffs ranging from less than \$5,000 to more than \$30,000.

[7] In addition, Griffin et al. (2003) find a strong relation between trade size and trader identity for their May 2000 through February 2001 sample of NASDAQ firms. Malmendier and Shanthikumar (2007) relate small and large trade imbalance to quarterly changes in institutional ownership and find significant correlations in the expected directions. In untabulated analysis, I relate the trade imbalance measures used in this paper to trades made through discount retail brokerage accounts from 1993–1996 and find the expected correlations. Finally, Barber et al. (2009) find significant correlations between trade initiation based on TAQ data and two brokerage data sets. Thus, small (large) trades are most likely to capture individual (institutional) trading.

[8] I modify the method used by Malmendier and Shanthikumar (2007) by excluding the 11 trading days around earnings announcements in calculating the "non-event-time" mean and standard deviation of the raw trade imbalance variables. Malmendier and Shanthikumar (2007) leave all trading days in their sample, as their analysis focuses on analyst buy/sell recommendations, a much more frequent event.

IV. RESULTS

Pricing Patterns for Series of Earnings Surprises

Because my definition of "series" differs from the various definitions of earnings strings used in prior literature, this section first replicates the primary analysis in Barth et al. (1999) for "series." Following Barth et al. (1999), I regress share price at quarter-end on net income per share, the position of a surprise in a series, and control variables for book value of equity, growth in book value of equity, earnings variance, debt-to-equity ratio, an indicator for banks and utilities, and indicators for different years. All control variables except book value of equity are interacted with net income. The key difference from Barth et al. (1999) is in the measure for an announcement's position in a series. This analysis uses indicators for $S = 1$, $S = 2$, $S = 3$, and $S \geq 4$, separately for top and bottom 30 percent surprises, whereas Barth et al. (1999) use an indicator for five consecutive years of increasing earnings, interacted with net income. Table 2 displays the results.

The results indicate that the first surprise in a series does not have an associated increase in price-to-earnings (P/E) multiples. In fact, the coefficient on $I(S = 1)$ is significantly positive (negative) for bottom 30 percent (top 30 percent) surprises, indicating that the market prices firms with $S = 1$ negative (positive) earnings surprises higher (lower) than would be predicted by a linear model of price to earnings, and other included variables, alone. This is not particularly surprising, since we might expect lower P/E multiples for firms with more extreme earnings surprises, where the market may expect those earnings to be less persistent. The key question is whether there are pricing patterns related with the *progression* of a series, as defined in this paper. The test statistics in the right-most column of Table 2 indicate that there are. Share price is significantly increasing (decreasing) for series of strongly positive (negative) SUE, for $S = 2$, 3, and $S \geq 4$, as compared to $S = 1$, 2, and 3, respectively, after controlling for the P/E multiples associated with net income and the other control variables. These results confirm that earnings surprise "series," as defined in this paper are associated with similar pricing patterns to the patterns documented in prior literature.[9]

Small, Medium, and Large Trade Reactions

This section presents results for the trading reactions of the different trade-size groups to a series of strong positive and strong negative surprises, testing H1. The primary specification is as follows:

$$\begin{aligned}\sum_{t-5}^{t+5} IMB^{abnormal}_{s,t} = {} & \beta^t_1 \mathrm{I}(lowSUE_e)*\mathrm{I}(S_e = 1) + \beta^t_2 \mathrm{I}(lowSUE_e)*\mathrm{I}(S_e = 2) + \beta^t_3 \mathrm{I}(lowSUE_e) \\ & *\mathrm{I}(S_e = 3) + \beta^t_4 \mathrm{I}(lowSUE_e)*\mathrm{I}(S_e \geq 4) + \beta^t_5 \mathrm{I}(highSUE_e)*\mathrm{I}(S_e = 1) \\ & + \beta^t_6 \mathrm{I}(highSUE_e)*\mathrm{I}(S_e = 2) + \beta^t_7 \mathrm{I}(highSUE_e)*\mathrm{I}(S_e = 3) + \beta^t_8 \mathrm{I}(highSUE_e) \\ & *\mathrm{I}(S_e \geq 4) + \beta^t_{SUE} SUE_e + \beta^t_{Q4} \mathrm{I}(Q_e = 4) + \beta^t_{Size} \ln(Size_e) + \beta^t_{IO} InstOwn_e \\ & + \beta^t_{TransIO} TransientInstOwn_e + \beta^t_{An} NumAn_e + \beta^t_{\ln(An)} \ln(NumAn)_e \\ & + \sum_{ind \in Industries} \beta^t_{ind} I(Industry(e) = ind) + \varepsilon_{e,t},\end{aligned} \tag{6}$$

---

[9] In untabulated analysis, I replicate the Barth et al. (1999) model using interactions between S-value and net income (NI), with qualitatively similar results. Results show a significantly negative coefficient on $NI * I(S = 1)$ and significantly less negative coefficients for $S = 2$ and 3. The difference for $S = 3$ and $S \geq 4$ is insignificant, p-value = 0.11, however the value for $S \geq 4$ is significantly higher than the values for $S = 1$ and 2.

*, **, *** Indicate statistical significance of coefficient estimates at the 10 percent, 5 percent, and 1 percent levels, respectively.

This table presents coefficient estimates from robust regressions of share price on Net Income (per share), indicators for S value for negative (bottom 30 percent SUE) and positive (top 30 percent SUE) series, and control variables. If a surprise is the first in a series of same-type surprises (top or bottom 30 percent Standardized Unexpected Earnings), then S = 1. If it is the second, then S = 2 and so on. The sample contains quarterly earnings surprises for NYSE firms from 1993 through 2002. The rightmost two columns provide p-values for one-tailed tests for the differences between coefficients, testing for decreases in coefficients on I(Bottom 30% SUE) ∗ I(S = X) with X and increases for Top 30 percent SUE.

Variable Definitions:
BVE = book value of equity;
NI = net income per share;
I(banks and utilities) = an indicator that takes the value 1 if a firm is a bank or utility;
Growth = annualized growth in BVE from five years prior;
Earnings Variance = standard deviation of earnings changes relative to the same quarter in the prior year, over five years;
Debt/Equity = book value of debt over book value of equity; and
NI ∗ X = interaction of NI and variable X.

where t is the trading day in event-time, e is the specific earnings surprise, and $I(lowSUE_e)$ ($I(highSUE_e)$) is an indicator that the standardized unexpected earnings surprise value for e is in the bottom 30 percent (top 30 percent) for the given period. $I(S_e = (\geq) X)$ is the indicator that the earnings surprise e occurs in position X (occurs in position X or greater) in a series, for $X = 1$, 2, and 3 ($X = 4$), as defined in Section III. The dependent variable is the sum of abnormal trade imbalance over trading days −5 through 5 in event time, to control for potential differences in the timing of small and large trader reactions.[10] The remaining variables are control variables. SUE_e is the standardized unexpected earnings value.[11] $I(Q_e = 4)$ is an indicator for the fourth fiscal quarter. $Ln(Size_e)$ is the log of market value at the end of the fiscal quarter. $InstOwn_e$ is the percentage of shares owned by 13F reporting institutions. Bushee (1998) and Ke and Petroni (2004) provide evidence that "transient" institutional investors are more likely to trade on earnings information and earnings patterns than other institutional investors. Thus, the model includes the percentage of shares owned by transient institutions, $TransientInstOwn_e$.[12] $NumAn_e$ and $\ln(NumAn)_e$ capture the number of analysts reporting earnings forecasts for event *e*. Finally, the model includes industry fixed effects, based on two-digit SIC codes. Coefficients on the variables $I(low/highSUE_e) * I(S_e = X)$ and $I(low/highSUE_e) * I(S_e \geq X)$ reflect the sensitivity of a trade group's trading to the given earnings surprise category, controlling for the other factors. Thus, H1 concerns changes in the differences of β_i coefficients for small and large traders as S_e increases. For example, H1 predicts that small traders' relative reaction will become more negative for a negative series, which implies that $(\beta_{1Small} - \beta_{1Large} > \beta_{2Small} - \beta_{2Large})$.

Table 3 displays results for each trade size group, as well as statistics for the difference in coefficient estimates for trades less than \$5,000 versus trades of at least \$50,000, the focus of this study. Panel A displays regression results, while Panel B provides test statistics for the differences in coefficients for different positions in a series. Figure 2 displays the results for the β_i coefficients graphically. The top (bottom) half of Figure 2 focuses on series of negative (positive) surprises. Figure 2 shows that in terms of the magnitude of reaction, controlling for other factors, the smallest traders react more negatively (positively) for surprises that are later in a negative (positive) series, with the exception of $S \geq 4$ positive surprises. The reactions of larger traders depend much less on a surprises' location within a series. The test statistics in Table 3 report the statistical significance of the numbers plotted in Figure 2.

Looking at the $S = 1$ line in the top half of Figure 2, and at column 6 of Panel A of Table 3, we can see that small traders react significantly more positively than large traders to the first negative surprise in a series, but looking at the $S = 3$ and $S \geq 4$ lines in Figure 2, and column 6, we can see that they react significantly more negatively than large traders to the third and fourth-or-later surprises in a negative series. Looking to Panel B of Table 3, we can see that the relative reaction of small traders versus large traders becomes significantly more negative for $S = 2$ versus $S = 1$ and $S = 3$ versus $S = 2$. The reaction becomes slightly less negative for $S \geq 4$ versus $S = 3$, but the decrease in negativity is not statistically significant, and the $S \geq 4$ relative reaction remains significantly more negative than the $S = 1$ relative reaction. Thus, the results for negative series for $S = 1$, 2, and 3 support H1. The results for $S \geq 4$ are not consistent with H1, but are not statistically significant in either direction.

It may be surprising that small traders react more positively to the first negative surprise in a series than large traders, and that the difference between the two trader groups is insignificant for the second surprise in a negative series. However, one possible interpretation is that small traders have more of a preference for "earnings momentum" than large traders, but small traders start with a weaker reaction to the earnings surprises than large traders at the beginning of a series. Then the "earnings momentum" preference would result in small traders gradually reacting similarly to large traders, and possibly passing them.

Focusing on positive series, column 6 of Panel A shows that small traders react insignificantly more negatively than large traders to the first positive surprise in a series and insignificantly more

---

[10] Results are similar using alternative event windows or excluding surprises without trading by the given trade-size group.

[11] I use three alternative models to control for the earnings surprise value, for robustness tests, with similar results. First, I include indicators for each SUE decile, second, standardized rank of SUE, and third, SUE, $I(SUE < 0)$, $SUE * I(SUE < 0)$ and SUE^2.

[12] I thank Brian Bushee for providing the transient institution data.

(continued on next page)

positively to the third and fourth. We can see these patterns in Figure 2. The increase in relative reaction is significant for $S = 3$ versus $S = 1$ and 2, and for $S \geq 4$ versus $S = 1$. We again see a decrease for $S \geq 4$ versus $S = 3$, but it is not statistically significant. Thus, the results for positive series for $S = 1$, 2, and 3 are generally supportive of H1, although they are not as strong as for negative series. The results for $S \geq 4$ are not consistent with H1, but are not significant in either direction. Consistent with Figure 2, the results are stronger and more consistent for negative series than for positive series. Including both the results for negative and positive series, I fail to reject H1.

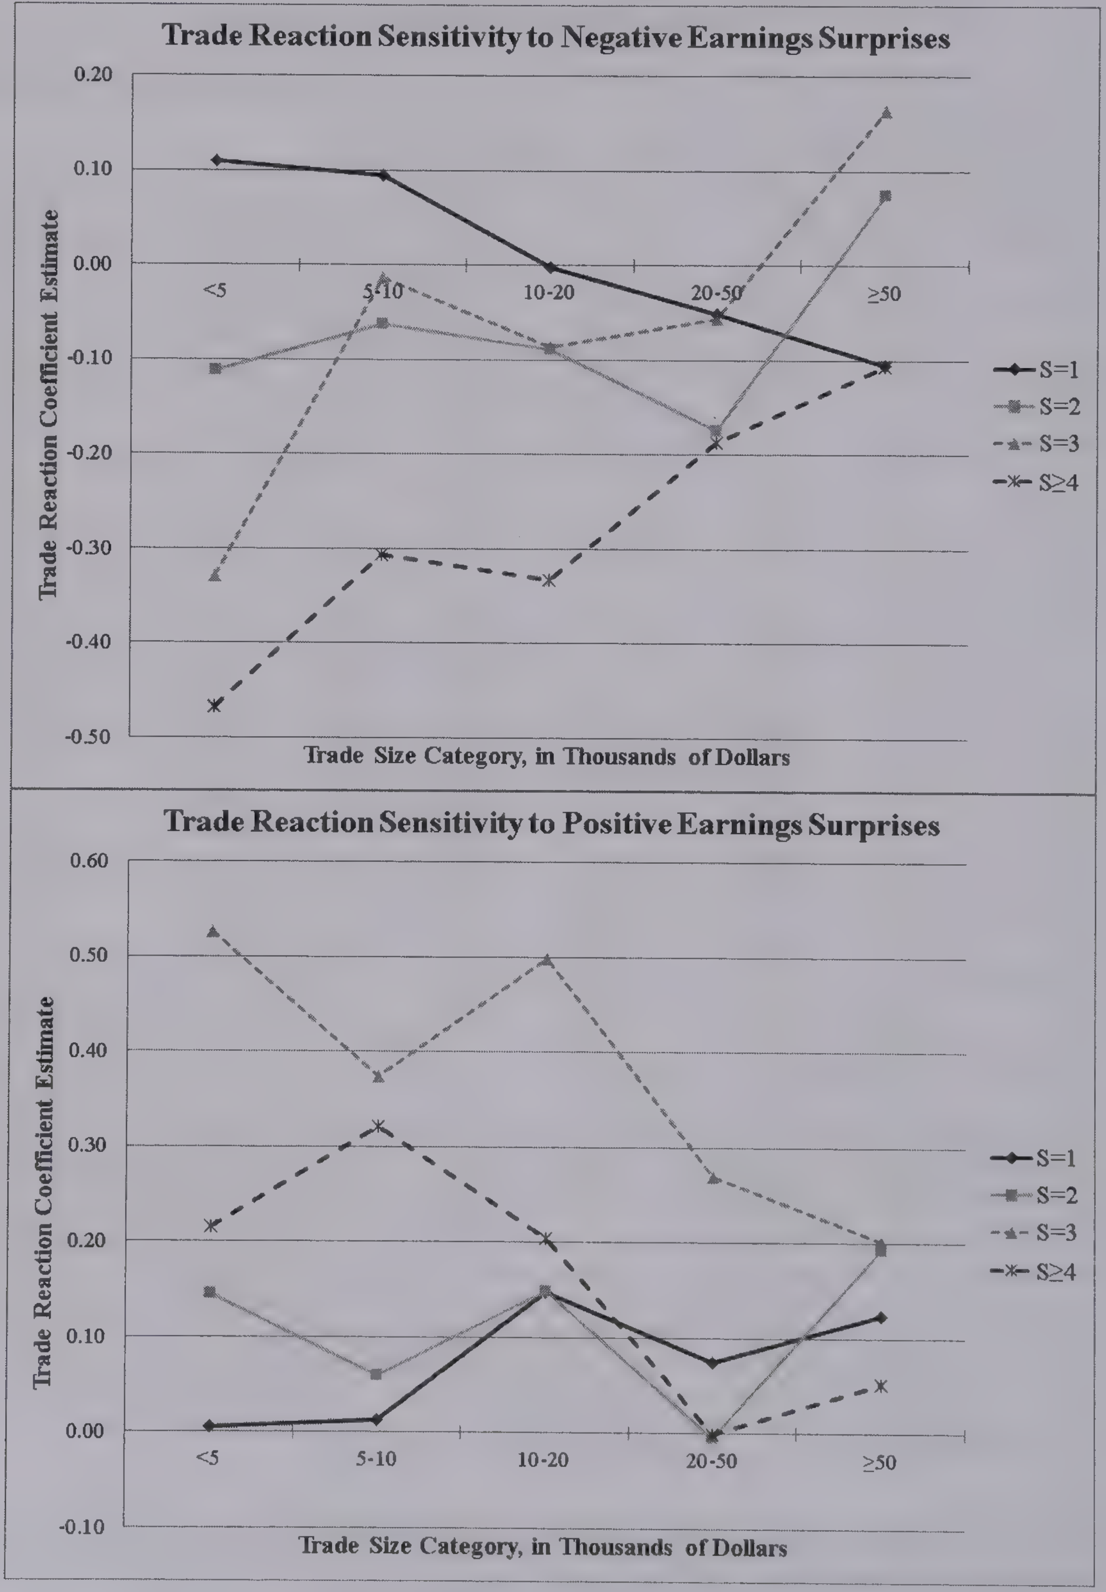
*, **, *** Indicate statistical significance of coefficient estimates at the 10 percent, 5 percent, and 1 percent levels, respectively.

Panel A presents coefficient estimates from regressions of abnormal trade imbalance, summed over trading days −5 through 5, on indicators for S value, separately for surprises in the top and bottom 30 percent of SUE, standardized unexpected earnings, and control variables. If a surprise is the first in a series of same-type surprises (top or bottom 30 percent), then S = 1. If it is the second, then S = 2 and so on. The sample contains quarterly earnings surprises for NYSE firms from 1993 through 2002. "Difference <5 versus ≥50" displays results for the difference between coefficient estimates for trades of <$5,000 and trades of ≥$50,000, estimated using a stacked regression, for the subset of observations with share price less than or equal to $50. For each column the sample is restricted to firm-days on which share price is low enough so that the given trade size is possible with a round lot of 100 shares. t-statistics are in parentheses. Standard errors are robust to heteroscedasticity and arbitrary within-firm correlation.

Panel B displays the differences between coefficient estimates reported in Panel A. p-values for the differences, based on F-tests, are in parentheses. Two-tailed tests are used for columns 1–5, and one-tailed tests are used for column 6. Significant values in Panel B column 6, at the 10 percent level, are shown in bold.

Variable Definitions:
I(Fiscal Quarter 4) = an indicator that takes the value 1 if the given quarter is the fourth quarter of the firm's fiscal year;
Ln(Size) = natural log of market value;
Institutional Ownership = percent of shares owned by 13F reporting institutions;
Transient Institution Ownership = percent of shares owned by institutions that are classified as "transient" following Bushee (1998);
Number of Analysts and ln(Number of Analysts) = number of analysts reporting forecasts of quarterly earnings for the firm in I/B/E/S and ln(Number of Analysts), respectively; and
Industry = as defined by the two-digit SIC code.

FIGURE 2
Trade Reaction to Earnings Surprises in a Series



This figure presents coefficient estimates from regressions of abnormal trade imbalance, summed over trading days −5 through 5, on indicators for S value for positive (top 30 percent) and negative (bottom 30 percent) SUE series, and control variables, as described in Table 3. The figure plots the relevant coefficient estimates from Table 3. Thus each point represents the sensitivity of the given trade-size-group's trade imbalance to earnings surprises with position S in a positive or negative series, controlling for other factors that may drive trade imbalance.

For completeness, Table 3 reports trade responses for each of five trade-size categories. As seen in Figure 2, the results indicate that as trade size grows, the reaction to the first ($S \geq 4$) negative surprise becomes more negative (less negative) in magnitude. Investors' reaction to the first (third) positive surprise is generally, although not monotonically, increasing (decreasing) with trade-size. The pattern for $S \geq 4$ is more mixed. These results, overall, suggest that there is a gradual progression between the behavior of the very small traders and the very large traders. In fact, for the relative reaction of trades between $5,000 and $50,000 versus trades larger than $50,000, three of the six relevant difference-of-differences for negative series are significantly negative and four of the six relevant difference-of-differences for positive series are significantly positive. Thus, it is not just small traders who exhibit a relative preference for "earnings momentum"; medium traders exhibit a preference relative to large traders as well.

The gradual progression is important to evaluating the potential market impact of earnings momentum trading. I directly examine the relation between the return response to earnings surprises and small trading in Section V. However, the appearance of relative earnings momentum trading among medium traders suggests that earnings momentum trading may have a larger price impact than if it appeared only for the smallest traders.

Finally, although Equation (6) includes the earnings surprise value, SUE, as a control variable, it still could be that pooling deciles 0–2 and deciles 7–9 affects results. I modify Equation (6) to include interaction terms between indicators for each SUE decile and S value. Results for the change in the relative reaction of small versus large traders with respect to S are reported in Table 4. The difference-of-difference results reported in Table 4 are analogous to column 6 of Table 3 Panel B. Results are generally consistent. No single decile appears to drive the overall results, nor are there statistically significant results contrary to H1 in any decile. The results by decile, as with the main results, are stronger for bottom 30 percent surprises than top 30 percent, and are in the opposite direction but statistically insignificant for $S \geq 4$ versus $S = 3$ for four of the six relevant deciles. Overall, these results show that the relative reaction of small versus large traders is stronger for earnings surprises later in a series whether those surprises are in the most extreme deciles or are closer to the median.

V. ADDITIONAL ANALYSIS

The Market Impact of Small Trades

Recent research has found that trading by retail investors and small traders is correlated both across investors and across securities (Kumar and Lee 2006; Barber et al. 2009). Because of this, the trades of even very small investors can have a significant impact on the market (see De Long et al. 1990; Baker and Wurgler 2006; Kumar and Lee 2006; Barber et al. 2009). The results presented in Section IV show earnings momentum trading by small and medium traders, relative to large traders, consistent with the previously documented market valuation of earnings growth consistency. This section directly tests the relation between small and medium trading and the concurrent market return around earnings announcements to verify that small and medium traders could be affecting returns.

Table 5 displays results for the relation of returns over days [−5, 5] with trading over the same window. The results show that trades of less than $5,000 exhibit a significant positive relation with concurrent returns. A one standard deviation change in the trade imbalance for trades less than $5,000 corresponds to returns of 0.047 percent over the same window, a change in returns of roughly 7 percent. The second column includes control variables for large trades and SUE (using the standardized rank of SUE, ranging from 0 to 1). While the magnitude of the coefficient on small trades decreases, it remains positive and statistically significant. Trades between $5,000 and $50,000 also relate significantly to concurrent returns. While this analysis does not establish

This table presents difference-of-difference results from regressions of small and large trade on indicators for SUE decile interacted with S value as well as control variables defined below and fixed effects for industry, as defined by the two-digit SIC code. If a surprise is the first in a series of same-type surprises (top or bottom 30 percent), then S = 1. If it is the second, then S = 2 and so on. The sample contains quarterly earnings surprises for NYSE firms from 1993 through 2002. The difference between coefficient estimates for trades of <\$5,000 and trades of ≥\$50,000 is estimated using a stacked regression for the subset of observations with stock price less than or equal to \$50. Standard errors are robust to heteroscedasticity and arbitrary within-firm correlation. p-values for the difference-in-differences are shown in parentheses, based on F-tests. One-tailed tests are used. Significant values are shown in bold.

Variable Definitions:
SUE = standardized unexpected earnings;
I(Fiscal Quarter 4) = an indicator that takes the value 1 if the given quarter is the final quarter of the firm's fiscal year;
ln(Size) = natural log of market value;
Institutional Ownership = percent of shares owned by 13F reporting institutions;
Transient Institution Ownership = percent of shares owned by institutions that are classified as "transient" following Bushee (1998); and
Number of Analysts and ln(Number of Analysts) = number of analysts reporting forecasts of quarterly earnings for the firm in I/B/E/S and ln(Number of Analysts), respectively.

---

causation, the results are consistent with smaller traders' earnings momentum trading contributing to the pricing patterns observed for series.[13]

Breaks in Series

Barth et al. (1999) show that the higher P/E multiples for earnings strings disappear after a "break" in the string, the first earnings decrease after a string of increases.[14] Examining breaks serves two purposes. First, as a robustness test, if omitted firm characteristics drive the increasing reaction pattern of small traders relative to large traders, then to the extent that these firm characteristics are persistent, they should affect trading in "Break" quarters as well. Second, the test relates to the prior

---

[13] Small and medium trades have a correlation coefficient of 0.47. If both small and medium trades are included in a regression of earnings-announcement returns, the coefficient on medium trades remains statistically significant, but the coefficient on small trades becomes insignificant.

[14] In untabulated analyses I estimate tests similar to those in Barth et al. (1999), but for breaks in a series. Consistent with the results for strings in Barth et al. (1999), I find that the premium for series decreases when a break occurs, becoming insignificant for breaks in positive series and decreasing significantly for breaks in negative series.

*, **, *** Indicate statistical significance of coefficient estimates, at the 10 percent, 5 percent, and 1 percent level, respectively.

This table presents coefficient estimates from regressions of cumulative raw returns, summed over trading days −5 through 5 around earnings announcement dates, on abnormal trade imbalance, summed over the same window, a constant, and the standardized rank of the earnings surprise (SUE) ranging from 0 to 1. The earnings surprise sample contains all earnings surprises for NYSE sample firms from 1993 through 2002. t-statistics are in parentheses. Standard errors are robust to heteroscedasticity and arbitrary within-firm correlation.

literature on breaks in strings. Table 6 presents results for Equation (6) augmented with indicators for a "break" in a series. "I(Break from Bottom 30 percent (Top 30 percent) SUE Series, S = (≥)X)" is the first surprise in the top 70 percent (bottom 70 percent) following a negative (positive) series of length X. For parsimony, the table presents only the coefficients on "Break" terms; however, all other variables in Equation (6) are included in the estimation.

The results in Table 6 indicate that small traders' relative reaction to a break does not depend on the length of a series. While small traders' relative reaction versus large traders becomes more negative (positive) for a longer negative (positive) series, their relative reaction at the break does not seem to vary systematically with the length of the series. For negative series, small and large trader reactions to breaks do not differ significantly for any of the four breaks examined. The difference-of-differences are also largely insignificant, with only one of the six being significant: a significant increase in the relative reaction for $S \geq 4$ versus $S = 3$. Small and large trader reactions to breaks in positive series only differ significantly for $S = 2$, and only two of the difference-of-differences are significant: a significant increase from $S = 1$ to $S = 2$, and $S = 1$ to $S \geq 4$. Again, there is no systematic pattern in the relative reaction to the break as S increases.

Overall, these results suggest that, first, omitted firm characteristics are not driving the main results, to the extent that these firm characteristics persist for at least one quarter. Second, these results suggest that small and large traders react similarly when a series breaks. This could be consistent with earnings momentum trading creating an "over-reaction" that is corrected when a series breaks, where small traders are more involved in the over-reaction, but large traders are equally involved in the correction.

Analyst-Based Earnings Surprise

One potential concern with the main results is that large traders' earnings expectations may be captured more accurately with analyst forecasts (Bhattacharya 2001; Battalio and Mendenhall

TABLE 7 (continued)

---

*, **, *** Indicate statistical significance of coefficient estimates in Panels A and C, at the 10 percent, 5 percent, and 1 percent levels, respectively.

This table presents regression results for several robustness checks and variations on the primary model, Equation (6). The models include control variables defined below and fixed effects for industry, as defined by two-digit SIC code. The dependent variable is abnormal trade imbalance, summed over trading days –5 through 5. If a surprise is the first in a series of same-type (top or bottom 30 percent) surprises, then $S = 1$. If it is the second, then $S = 2$ and so on. The sample contains quarterly earnings surprises for NYSE firms from 1993 through 2002. "Difference <5 versus ≥50" displays results for the difference between coefficient estimates for trades of <$5,000 and trades of ≥$50,000, estimated using a stacked regression, for the subset of observations with stock price less than or equal to $50. For each column the sample is restricted to firm-days on which stock price is low enough so that the given trade size is possible with a round lot of 100 shares. For Panels A and C, t-statistics are in parentheses. Standard errors are robust to heteroscedasticity and arbitrary within-firm correlation. The specific variations are described below. Panels B and D display the differences between coefficient estimates reported in Panels A and C, respectively. p-values for the differences, based on F-tests, are in parentheses. Two-tailed tests are used for columns 1–3 and 5–7, and one-tailed tests are used for columns 4 and 8. Significant values in Panels B and D, columns 4 and 8, at the 10 percent level, are shown in bold.

Panel A presents results for two alternative earnings surprise measures. The column "Analyst-Based Surprise" presents results where the earnings surprise and corresponding surprises series (i.e., top/bottom 30%, $S = 1$, $S = 2$, etc.) are determined based on analyst-forecasts. For columns 1–4, a "negative surprise" ("positive surprise") is defined as a surprise in the bottom 30 percent (top 30 percent) of analyst-based surprises. The column "Positive/Negative SUE" presents results for the main standardized unexpected earnings (SUE) measure, where "S" is defined using all positive (negative) surprises rather than only those in the top (bottom) 30 percent.

Panel C presents results for alternative trade imbalance measures, in which the dependent variable is abnormal trade imbalance with additional adjustments. Column "a" presents results where the dependent variable is abnormal trade imbalance with additional adjustments for response to prior day, week, month, and quarter returns. Column "b" presents results where the dependent variable is abnormal trade imbalance with adjustments for calendar-time effects, prior returns, and prior trade-imbalances.

Variable Definitions:
SUE = earnings surprise value for Panel A, columns 4–6 and Panel C and analyst-based earnings surprise for Panel A, columns 1–3;
I(Fiscal Quarter 4) = an indicator that takes the value 1 if the given quarter is the final quarter of the firm's fiscal year;
ln(Size) = natural log of market value;
Institutional Ownership = percent of shares owned by 13F reporting institutions;
Transient Institution Ownership = percent of shares owned by institutions that are classified as "transient" following Bushee (1998);
Number of Analysts and ln(Number of Analysts) = the number of analysts reporting forecasts of quarterly earnings for the firm in I/B/E/S and ln(Number of Analysts), respectively.

significantly negative coefficient for I(Bottom 30 percent Surprise) $*$ I($S = 1$), there is no evidence of large traders reacting more strongly as either the positive or negative series progresses. Coefficient differences, presented in Panel B, are insignificant. In untabulated analyses, I examine trade reactions for each earnings surprise decile, analogously to Table 4, and find no evidence of large traders reacting more strongly for series.

While small and medium trading is not the focus of this test, I document results for completeness. Focusing on column 4, the difference between small and large trades, there is weaker evidence for an "increasing reaction" for small traders relative to large traders than in the main tests. For surprises in the bottom 30 percent, two of the six relevant differences are significant, and for surprises in the top 30 percent, three of the six differences are significant. Given that the analyst-based expectations model is less likely to capture small trader expectations (Bhattacharya 2001; Battalio and Mendenhall 2005), it is not surprising that I find less evidence of an increasingly strong relative reaction.

Series of Positive and Negative SUE

The primary analysis focuses on strong positive (top 30 percent of SUE) and strong negative (bottom 30 percent) surprises to eliminate the possible confounding effects of "expected" small surprises, which is important when comparing small and large traders who may view small surprises differently. However, prior literature on strings focuses on positive earnings changes (e.g., Barth et al. 1999; Myers et al. 2007; Ke et al. 2003; Ke and Petroni 2004). Thus, this subsection examines trading for series of positive ($SUE > 0$) and negative ($SUE < 0$) earnings announcements. For clarity, I label "S" values defined using $SUE > 0$ and $SUE < 0$ as $S_{+/-}$.

Using this definition, all surprises have a value of at least 1 for $S_{+/-}$. In order to avoid collinearity with the included industry fixed effects, I exclude the term for I(Negative Surprise) $*$ I($S_{+/-} = 1$). The results are reported in Table 7, Panels A and B. There is no evidence of a more negative reaction from small traders, relative to large traders, as a negative series progresses. However, for positive series the difference between small and large trades becomes significantly more positive as the series continues. The difference is monotonically increasing, with statistically significant differences for $S_{+/-} \geq 4$ versus $S_{+/-} = 1$, 2, and 3, and for $S_{+/-} = 3$ versus $S_{+/-} = 1$. Thus, results are qualitatively similar for "positive" series as they are for "strong positive" series, but there is no evidence of increasing reactions for purely "negative" series as there is for "strong negative" series. Given that the prior literature has focused on strings of positive earnings changes, this analysis indicates that the primary results in the paper extend to a definition of series that is closer to that used in prior literature, strengthening the link between the small/large trade results documented in this paper and the price/return results from prior literature.[15]

Alternative Trade Imbalance Measures

This subsection presents two robustness tests using alternative trade-imbalance measures that control directly for prior returns. On average, a firm with prior positive (negative) earnings surprises will have had prior positive (negative) returns. It is possible that a naïve reaction to past returns would affect trading during a series.

---

[15] I estimate a model including the interaction terms between $S_{+/-}$ indicators and SUE decile indicators. The results show slightly more evidence of small traders reacting more negatively, relative to large traders, for surprises that are later in a string of negative surprises, with seven of 18 difference-of-difference coefficients for deciles 0, 1, and 2 being significantly negative, and 1 being significantly positive. The results also show slightly weaker evidence for positive series, with four of 18 difference-of-difference coefficients being significantly positive. However, the coefficient patterns are consistent with small traders reacting more strongly, relative to large traders, for surprises later in a positive or negative string, controlling for earnings surprise decile.

For the first measure, I regress abnormal trade imbalance on cumulative abnormal returns over the prior day, week, month, and quarter: trading day intervals [−1], [−5, −2], [−20, −6] and [−60, −21]. Return-adjusted abnormal trade imbalance is defined as the residual from this regression.[16] Table 7, Panel C reports results from estimating Equation (6) using the return-adjusted trade-imbalance measure. Focusing on column 4, the difference between small and large traders, we can see that small traders react increasingly negatively to a series of bottom 30 percent surprises, relative to large traders. Five of the six relevant difference-of-differences in Panel D, column 4 are statistically significant. While the results are not as strong for positive series, they are similar to the main results reported in Table 3, with statistically significant increases in the difference between small and large trader reactions from $S = 1$ and 2, to $S = 3$ and $S = 1$, to $S \geq 4$.

Based on Chordia et al. (2002) and Frieder (2008), I define a second measure that controls for calendar-effects, serial correlation in the trade imbalance variable, and dependence of trade imbalance on prior returns.[17] The right half of Table 7, Panels C and D reports regression results and tests for differences in coefficients, respectively, using this alternative trade imbalance measure. The results are qualitatively similar to the primary results, and similar to the results for return-adjusted abnormal trade imbalance. In untabulated analyses, I replicate Table 4 using both the return-adjusted trade measure and the trade measure adjusted for calendar-effects. Results are similar to those presented in Table 4 and slightly stronger, using these alternative abnormal trade measures.

The results presented in Table 7, Panels C and D further support the results presented in Section IV, i.e., that small traders react more strongly to a series of similar earnings surprises, relative to large traders. While the primary specification in Equation (6) controls for important factors that may drive trade, the results in Panels C and D show that results are robust to controlling explicitly for prior returns, calendar-time effects, and prior trade imbalances.[18] If anything, results for negative series and $S \geq 4$ are more strongly consistent with H1 once I explicitly control for prior returns.

VI. CONCLUSION

This paper documents investor reactions to the time-series of earnings surprises. The results document that smaller traders react generally more negatively relative to large traders as a series of strongly negative surprises progresses, and more positively for the first three positive surprises in a series of positive surprises. These results are robust to many method variations and controls. The paper also documents that the announcement-period market reaction to earnings surprises is significantly related to small and medium traders' concurrent trading. Together, these results are consistent with the price/returns patterns documented in Barth et al. (1999), Myers et al. (2007), and Lev et al. (2008) reflecting stronger "earnings momentum" trading on the part of small and medium traders than on the part of large traders, at least for the first three quarters in a series. Given differences in small and large traders' sophistication, but the lack of systematic differences in their risk preferences, this suggests that the price/return patterns early in a series may be due more to unsophisticated investors than to changes in firm risk.

---

[16] The untabulated results indicate that large traders are "momentum" traders, buying more strongly when prior returns have been higher, while small and medium traders appear to be "contrarians," consistent with prior evidence (Grinblatt et al. 1995; Kaniel et al. 2008).

[17] Shanthikumar (2004) describes details of the procedure and insights for calendar-effects in returns.

[18] I conduct a variety of additional robustness tests. The primary results are robust to the inclusion of fixed-effects for each security, to control for any potential variation in trade imbalance across firms. The results are robust to the inclusion of fixed effects for each of the 40 sample quarters as well as the inclusion of fixed effects for each of 100 groups defined by size decile and book-to-market decile.

The small and large investor reaction to earnings series documented here is also relevant to behavioral finance models that predict that investors will react more strongly as similar information is released (Barberis et al. 1998; Daniel et al. 1998; Mullainathan 2002). These models show that increasing investor reactions can explain both short-run momentum and long-run mean-reversal in returns. There is disagreement on whether investors display a preference for consistency in laboratory settings (Bloomfield and Hales 2002; Asparouhova et al. 2009). This paper documents that small traders display a relative preference for consistency in market trading.

The trading evidence provided in this paper shows that, relative to large traders, small traders are more sensitive to earnings information later in a series of similar surprises, particularly for negative series and for the first three quarters of positive series. By stepping beyond aggregate market response measures such as price and returns, these results increase our understanding of the market's reaction to the time-series pattern of earnings information.

Audit Quality and Auditor Reputation: Evidence from Japan

Douglas J. Skinner
The University of Chicago

Suraj Srinivasan
Harvard University

ABSTRACT: We study events surrounding ChuoAoyama's failed audit of Kanebo, a large Japanese cosmetics company whose management engaged in a massive accounting fraud. ChuoAoyama was PwC's Japanese affiliate and one of Japan's largest audit firms. In May 2006, the Japanese Financial Services Agency (FSA) suspended ChuoAoyama for two months for its role in the Kanebo fraud. This unprecedented action followed a series of events that seriously damaged ChuoAoyama's reputation. We use these events to provide evidence on the importance of auditors' reputation for quality in a setting where litigation plays essentially no role. Around one quarter of ChuoAoyama's clients defected from the firm after its suspension, consistent with the importance of reputation. Larger firms and those with greater growth options were more likely to leave, also consistent with the reputation argument.

Keywords: *audit quality; auditor reputation; Japan.*

Data Availability: *All data in the paper are publicly available from the sources described in the text.*

We thank Joachim Gassen (AAA discussant), Kazuo Kato, Urooj Khan, Thomas Lys, Yosh Matsumoto, Masumi Nakashima, Tomomi Takada, Stephen Taylor, Joe Weber, Steve Kachelmeier and John Harry Evans III (editors), the two anonymous reviewers, and workshop participants at the 2009 AAA Annual Meeting in New York City, Boston University, University of Edinburgh, Emory University, Harvard Business School, London Business School, Manchester Business School, University of Melbourne, Massachusetts Institute of Technology, the 2009 NUS-Notre Dame CARE Conference, The Ohio State University, University of Washington, Yale School of Management Summer Accounting Conference, and Wharton School of Business for helpful comments on previous versions. We also thank Robert Eccles, Masako Egawa, Michael Krzus, Andrew Popham, Reiko Sato, Yoshiko Shibasaka, Hanado Yasuhito, Nabuo Sato, the staff of the Certified Public Accountants and Auditing Oversight Board at the Japan Financial Services Authority, and the staff of the Harvard Business School Japan Research Office for their valuable assistance in helping us understand the Japanese audit industry. Gang Huang, Kei Ikenishi, Kei Kondo, Allan Sumiyama, and Alice Thieu provided valuable research assistance. We are grateful to the Initiative on Global Markets at The University of Chicago, Booth School of Business for financial support.

Editor's note: Accepted by John Harry Evans III, with thanks to Steven Kachelmeier for serving as editor on a previous version.

I. INTRODUCTION

High-quality external auditing is a central component of well-functioning capital markets. The accounting literature focuses on two principal forces that motivate auditors to deliver quality—a litigation/insurance incentive and a reputation incentive. Under the first motive, if auditors are legally liable for audit failures, then they have an incentive to deliver high-quality to avoid the costs of litigation. The insurance role arises because investors prefer larger audit firms as these firms can better meet investors' legal claims, thus providing investors' financial recourse against poor audit quality. Under the second motive, auditors have reputational incentives to avoid audit failures because audit quality is valuable to clients and so priced in the market for audit services. Under this view, clients defect to other auditors when an audit firm's reputation for quality deteriorates.

Empirically, it is difficult to separate the effects of litigation/insurance from those of reputation in markets such as the U.S. because the largest audit firms have both the largest litigation incentives and the strongest reputations. We study recent events in Japan where auditors' legal liability is essentially nonexistent. Specifically, we study the case of ChuoAoyama, PricewaterhouseCoopers' (PwC) former affiliate in Japan, which was implicated in a major accounting fraud at Kanebo, a large Japanese cosmetics company. This case provides a good setting for examining the importance of auditor reputation absent the confounding effects of litigation.

In May 2006, regulators in Japan took the unprecedented step of suspending ChuoAoyama's operations for two months as punishment for its role in the Kanebo fraud. Also in response to these events, and at about the same time, PwC adopted a "two-firm strategy" in Japan, under which it undertook to (1) address the audit-quality problems at ChuoAoyama, which it rebranded Misuzu, and (2) establish a new, smaller "high-quality" affiliate in Japan, which it named Aarata. A select group of Japanese clients that included Sony and Toyota, as well as large multinational clients with operations in Japan, moved to Aarata. The revelation in December 2006 of serious accounting irregularities at Nikko Cordial, another prominent ChuoAoyama client, ultimately caused Misuzu to be shut down.

Firms with a reputation for credible financial reporting are likely to change auditors when their audit quality is questioned to avoid the capital market consequences of potentially unreliable financial reporting (Hennes et al. 2011). However, these benefits must be balanced against the costs of switching auditors. First, firms face search costs in identifying and hiring a new audit firm. Second, incumbent auditors develop firm-specific knowledge and expertise about the client that is costly for a new auditor to acquire (DeAngelo 1981).[1] Third, the supply of auditors is constrained in the short run, especially when many firms are looking for new auditors at the same time (Kohlbeck et al. 2008; Ramnath and Weber 2008), as is likely to be the case in our setting.

Prior research finds that local audit office effects are important in explaining auditor attributes such as client dependence (Reynolds and Francis 2000), industry expertise (Ferguson et al. 2003; Francis et al. 2005; Basioudis and Francis 2007), and audit quality in general (Francis and Yu 2009; Chaney and Philipich 2002; Nelson et al. 2008). This suggests that there is a local office effect on audit quality as well as an overall audit firm effect. If audit-quality problems are confined to a particular practice office, then investors are less likely to be concerned about clients of other offices of the audit firm. Our setting provides an unusual instance in which audit quality was perceived to be low across an entire audit firm. As explained below, PwC effectively acknowledged that it could not consistently deliver quality in its Japanese operations by dividing ChuoAoyama into two firms, one of which (Aarata) it characterized as being of higher quality.[2] The view that ChuoAoyama's problems were pervasive was reinforced by the regulator's decision to suspend its operations.

---

[1] The "low balling" literature suggests that audit firms price the initial year of an audit engagement below cost to win the engagement with the expectation that the initial losses will be offset by higher fees in the future (Kanodia and Mukherji 1994). Therefore, the higher fees from an auditor change may not be immediately evident.

We find that roughly one-quarter of ChuoAoyama's clients dropped the firm when the extent of its audit-quality problems became apparent, but before it became clear that it would be wound down.[3] Firms with a greater demand for audit quality—larger firms and those with greater growth options—were more likely to leave ChuoAoyama, consistent with our argument that switches were driven by concerns about audit quality.

It would be more difficult to attribute these switches to concerns about audit quality if client firms simply followed their existing audit partners to new audit firms after the suspension was announced. To investigate this, we compare the identity of the audit partners who sign the audit report before and after auditor changes. We first show that there is no overlap in the identity of audit partners who signed audit reports before and after switches for those ChuoAoyama clients that left the firm after the suspension was announced (i.e., those that switched in May, June, and July 2006). In contrast, for those clients that switched auditors after the decision to close the firm in February 2007, there is a good deal of overlap in audit partners who signed audit reports before and after switches. These results are consistent with our interpretation that the switches in 2006 are driven by concerns about audit quality, while those in 2007 are driven by the revelation that the firm would be wound down.

We also use an event study to investigate whether ChuoAoyama's clients suffered declines in equity value as information about the firm's lower audit quality was revealed. We find a statistically significant but small negative reaction to the set of events that collectively revealed the decline in quality. However, this event study likely lacks power because of the relatively long period over which these events unfolded and the associated difficulty of isolating exactly when news about audit quality reached market participants.

Taken as a whole, our evidence supports the view that auditor quality and reputation are important in an economy where litigation does not provide auditors with incentives to deliver quality.[4] Most prior literature finds mixed support, at best, for the importance of auditor reputation as a driver of audit quality (Lennox 1999; Willenborg 1999; Khurana and Raman 2004). Consistent with our findings, Weber et al. (2008) find evidence of client switching when fraud at ComROAD AG raised questions about audit quality at KPMG in Germany, where litigation costs are relatively small. Our findings are stronger than those in Weber et al. (2008), and exploit unusual features of the Japanese setting to further strengthen the interpretation that these results are driven by reputation.

There are both similarities and differences between the events at ChuoAoyama and those surrounding the demise of Arthur Andersen in the U.S. The two sets of events are similar in that Andersen's ultimate demise, which resulted from its failed audit of Enron, was preceded by problems with its audits of Waste Management, Sunbeam, and the Baptist Foundation of Arizona.[5]

---

[2] Our characterization of Aarata as the higher quality firm follows the position of PwC's CEO Samuel DiPiazza, who said, "Aarata's limited size reflected the availability of staff who met the firm's performance standards" (*Financial Times* 2007). Our interviews with former personnel of ChuoAoyama, auditors from other audit firms, company managers, academics in Japan, the senior staff of the Japan Institute of Certified Public Accountants, and the Auditing Oversight Board at the Japanese FSA confirm the view that Aarata was the higher-quality firm.

[3] Approximately one-quarter of ChuoAoyama's clients moved to other auditors soon after the suspension was announced. We provide evidence and arguments later in the paper to show that this suspension did not make it likely that ChuoAoyama would subsequently be wound down and that, as of the time of the suspension, most parties viewed the firm as being viable in the long run.

[4] Murase et al. (2010) also examine auditor switching around the time of the ChuoAoyama events. Broadly similar to our findings, these authors find that clients with larger agency costs tended to switch to auditors unaffiliated with PwC, while clients with larger switching costs tended not to change auditors.

[5] As reported by Ball (2009, 292), Andersen settled lawsuits related to these audits for $27 million in the case of Waste Management (including the SEC settlement), $110 million in the case of Sunbeam, and $217 million in the case of the Baptist Foundation of Arizona.

Most notably, Andersen's audits of Waste Management during the 1990s resulted in what was, at the time, an unprecedented settlement with the SEC, which included a $7 million fine and a permanent injunction against further violations. It was this settlement that set the stage for the firm's subsequent criminal indictment in the Enron case.

Prior to the revelation of the fraud at Kanebo, ChuoAoyama had been implicated in accounting frauds at Yaohan Japan, Yamaichi Securities, and Ashikaga Bank. But it was its involvement in the fraud at Kanebo, like Andersen's involvement in the fraud at Waste Management, that resulted in the unprecedented action by regulators. As was the case with Andersen at Waste Management, the regulatory consequences of ChuoAoyama's involvement in the Kanebo fraud were unprecedented but did not threaten the existence of the firm. Consequently, the clients that switched from ChuoAoyama after the suspension was announced, unlike those that left Anderson following that firm's indictment, did not leave because of the imminent closure of the firm. Thus, it is more appropriate to analogize the events in the Kanebo/ChuoAoyama case to those at Waste Management/Andersen than to those of the Enron case. As indicated above, it was the subsequent revelation of accounting irregularities at Nikko Cordial that resulted in the closure of ChuoAoyama.

The more significant difference between the two sets of events, however, is the absence of litigation in the Japanese setting. In the U.S., client losses attributable to Andersen's association with Waste Management could be due to reputational effects, legal consequences, or some combination thereof (as its legal costs mounted, the resources available to meet future legal claims at Andersen were diminished, reducing the insurance value of its audit services).[6] Thus, the Japanese setting provides a substantially cleaner test of the market response to an auditor's loss of reputation.

Our setting is also different from that of Weber et al. (2008) in at least two respects. First, at the time of the events described here, litigation against auditors was largely unavailable to investors in the Japanese market. In contrast, auditors could be sued in Germany although damages were capped at relatively low amounts. Second, in our setting, government regulators clearly signaled the systemic nature of the audit-quality problems at ChuoAoyama by announcing a firm-wide suspension; the severity of the regulator's actions were, at the time, a shock to the Japanese financial community, which had been expecting a modest fine. In contrast, the revelations of audit-quality problems at ComROAD AG in Germany were revealed gradually through the press.

There a number of reasons that the suspension of ChuoAoyama in May 2006 did not raise questions about the firm's survival. First, there was no perception that the suspension was a "death penalty" for ChuoAoyama. The suspension was deliberately timed to begin on July 1, after the conclusion of the annual reporting cycle including annual shareholder meetings in June. Second, the Japanese Institute of Certified Public Accountants discouraged poaching by competitor audit firms (Kyodo News International 2006), an action that would be unlikely if the firm's survival was in jeopardy. Third, there is no evidence that partners were leaving ChuoAoyama as clients defected between May and July 2006. If partners had feared that ChuoAoyama would shut down, we would expect to see departure of audit partners due to career concerns. Fourth, the suspension did not prevent clients from returning to ChuoAoyama when the suspension ended, and most did return. Fifth, the events we describe show that the actual end of Misuzu, the renamed ChuoAoyama, came after the revelation in December 2006 of serious accounting irregularities at another ChuoAoyama client, Nikko Cordial. Finally, our evidence shows that after the first set of client defections from May to July 2006, there was no meaningful client switching until March 2007, when an orderly transition of Misuzu clients to other audit firms began.

---

[6] Ball (2009) reports that Andersen began to lose clients in 2000 and the first part of 2001, before the problems at Enron came to light.

The next section provides more details about the Kanebo fraud, the role of ChuoAoyama, a discussion of prior literature, and empirical predictions. Section III describes our sample and provides empirical evidence. Section IV offers a summary and conclusions.

II. THE DOWNFALL OF CHUOAOYAMA AND EMPIRICAL PREDICTIONS

The Kanebo Fraud and the Downfall of ChuoAoyama

In 2004 Kanebo, a longtime ChuoAoyama client, revealed a massive accounting fraud and began an internal investigation that resulted in Kanebo dropping ChuoAoyama as its auditor. Appendix A lists key events in the case. In April 2005, Kanebo revealed that the accounting fraud amounted to an overstatement of income of around 200 billion yen ($1.9 billion) for the fiscal years 1999–2003. After correction, the restated financial statements showed a cumulative loss during that time period of 207 billion yen.[7] While Kanebo was the largest corporate fraud in Japanese history (Hosono 2008), ChuoAoyama had previously been implicated in other accounting frauds, including Yaohan Japan Corp. (1997), Yamaichi Securities (1999), and Ashikaga Bank (2000). In July 2005, three former Kanebo executives were arrested and government prosecutors searched ChuoAoyama's offices. Over the next few months, government prosecutors indicted three ChuoAoyama auditors and ChuoAoyama's board resigned.

PwC took a number of steps to preserve its reputation in the wake of these events. First, late in 2005, Samuel DiPiazza, worldwide head of PwC, traveled to Japan to meet with Japanese regulators, ChuoAoyama executives, and management of important clients, largely to assure them of PwC's commitment to correcting the problems at ChuoAoyama. Second, early in 2006 PwC sent high-level audit personnel from the U.S. and U.K. to take corrective action at ChuoAoyama. In addition to making operational and training improvements at ChuoAoyama, PwC considered forming a new, smaller audit firm that would operate independently of ChuoAoyama. PwC identified four of the firm's Japanese staff, all former Aoyama (Price Waterhouse) partners, as candidates to head the new firm.[8] However, the Japanese leadership of ChuoAoyama resisted this change, arguing that such a drastic step was unnecessary.

During the trial of the Kanebo executives, the accused ChuoAoyama auditors admitted their complicity in the fraud, a revelation that came as a surprise to others in the firm. In late March 2006, the former ChuoAoyama auditors themselves went on trial and pled guilty to the charges. These events made it more difficult for ChuoAoyama leadership to argue that their initial reforms were sufficient. PwC then decided to proceed with its "two-firm strategy" of forming a new, smaller firm, to be known as PwC Aarata, and rebranding the rest of ChuoAoyama as Misuzu Audit Corp. When PwC announced this strategy in May 2006, it indicated that Aarata would audit PwC's international clients in Japan and, in return, PwC would audit the international operations of Aarata's Japanese clients. Most of ChuoAoyama's clients and staff went to Misuzu, which was essentially a reconstituted ChuoAoyama, while a smaller group of clients and, arguably, those of most strategic importance to PwC internationally (Sony and Toyota being the most prominent examples) went to Aarata.[9] Consistent with its higher quality status, Aarata was not subject to sanctions and was allowed to conduct business during the ChuoAoyama suspension period.

---

[7] Japanese GAAP first required consolidated financial reporting in the late 1990s. The Kanebo fraud involved the failure to include 14 poorly performing subsidiaries in its consolidated financial statements (Hosono 2008; Hawkins et al. 2010).

[8] ChuoAoyama was formed in April 2000 from a merger between Chuo Audit Corp. (the Coopers & Lybrand affiliate) and Aoyama (the Price Waterhouse affiliate). Chuo was responsible for the three audit failures mentioned in the text. At the time of the merger, Chuo, which contributed 310 partners to the merged firm, was much larger than Aoyama, which contributed 37 partners.

[9] We provide evidence below that most former Aoyama clients still audited by ChuoAoyama in fiscal year 2006 went to Aarata, but only a small fraction of former Chuo clients went to this firm. This is consistent with the suggestion that Aarata was a reconstituted version of Aoyama, the original Price Waterhouse affiliate.

On May 10, 2006, the Japanese Financial Services Agency (FSA) ordered a two-month suspension of the audit operations of ChuoAoyama beginning July 1, 2006.[10] With some exceptions, the rule effectively forced ChuoAoyama to suspend business for two months. ChuoAoyama's clients took one of three actions as a result. First, some firms appointed an interim auditor for the period of the suspension and returned to ChuoAoyama when it resumed business as Misuzu. Second, other firms returned to Misuzu after the suspension without appointing an interim auditor. Third, some firms chose a different auditor and did not return to Misuzu, including approximately 50 firms that switched to Aarata. While companies in Japan are required to have an external auditor at all times, the FSA stated following the suspension order that "realistically speaking we are not sure whether all companies will be able to name a temporary auditor" (*Financial Times* 2006), referring to constraints on the availability of alternative auditors. This suggests that the FSA did not enforce the rule and there existed some level of regulatory forbearance on this issue.[11]

In December 2006, allegations of serious accounting irregularities at Nikko Cordial, another ChuoAoyama client, came to light. To preempt further regulatory action and reputational damage, PwC announced on February 20, 2007 that they would terminate Misuzu. PwC proposed to transfer all staff and clients to other audit firms after fiscal 2006 audits were completed in the spring of 2007.[12]

Previous Literature and Empirical Predictions

Previous literature provides two types of evidence on auditor reputation. Both lines of research rely on the premise that when reputation is important in the audit market, observable declines in audit firm quality will lead to adverse consequences for its clients. One line of research examines auditor switching around events that signal a decline in an audit firm's quality. Lennox (1999) analyzes audit failures in the U.K. from 1987 to 1994 and finds that larger auditors are more likely to be sued, consistent with the liability argument, but that clients generally do not drop auditors following audit failures as the reputation argument would predict. Shu (2000) finds that, consistent with the litigation argument, auditor resignations reflect increases in client litigation risk as well as changes in audit firm characteristics. Also consistent with the litigation argument, she finds that clients tend to move to smaller audit firms after a large auditor resigns, and that there is a significant negative stock price reaction to these events.

Barton (2005) examines auditor switches after the market learned about the scope of Andersen's audit failure at Enron. However, the events at Enron and the associated demise of Andersen occurred over a short period of time, making it difficult to distinguish whether the auditor switches reflected primarily reputation concerns versus being forced by the Andersen closure. Barton (2005) finds that 95 percent of the switches away from Andersen occurred after Andersen was indicted in March 2002.

---

[10] In the only previous business suspension order against an audit firm in Japan, Mizuho Audit Corporation, a smaller audit firm, was suspended for one year on October 15, 2002.

[11] Under the Japanese Financial Instruments and Exchange Act, an annual securities report must be submitted within three months of the end of that fiscal year. ChuoAoyama's suspension was timed to start from July 1 as most Japanese companies end the fiscal year on March 31 and complete their annual reports and hold meetings by the end of June. Under the Companies Act in Japan, a company is required to have an auditor at all times. Thus, ChuoAoyama's clients needed to find interim auditors during the two months of the suspension period.

[12] There is some ambiguity about who initiated the closure of Misuzu. Some articles, including those that cite Samuel Di Piazza, then CEO of PwC, characterize this as a decision taken by PwC internationally (*Financial Times* 2007). Other sources indicate that the local management of Misuzu made the decision in order to preempt its loss of clients as a result of the cumulative effect of the accounting scandals (see *Asahi Shimbun* 2007; *Japan Times* 2007). These actions enabled the firm to avoid "losing face" by having to close involuntarily and lay off staff. Thus, soon after the new fraud came to light, Misuzu cooperated with Tohmatsu, ShinNihon, and AZSA (the remaining Big audit firms) to transfer its audit personnel and clients to those other firms. There is little doubt, however, about the basic cause and effect—the revelation of the accounting fraud at Nikko Cordial quickly resulted in the demise of Misuzu.

A second line of research examines the stock price reaction to events that change market perceptions of the quality of services provided by a given audit firm. Menon and Williams (1994) and Baber et al. (1995) examine the reaction of client stock prices to the bankruptcy of Laventhol and Horwath, at the time the seventh largest audit firm in the U.S. Both studies report a significant negative reaction to the announcement, consistent with both the insurance and reputational roles for auditors. Chaney and Philipich (2002) examine the stock price reaction for clients of Andersen when it revealed document shredding related to the Enron audit. They find a significantly negative reaction, which they attribute to Andersen's loss of reputation, although Nelson et al. (2008) contest this interpretation because of confounding news on the event dates. Cahan et al. (2009) investigate the stock price reaction to Enron-related events for the non-U.S. clients of Andersen and find evidence of significantly negative reactions, which supports the importance of reputation. Krishnamurthy et al. (2006) also provide evidence that Andersen clients suffered negative market returns around the time of Enron-related events and relate these returns to cross-sectional measures of audit quality.

To more clearly distinguish the insurance and reputational explanations, Weber et al. (2008) examine an audit failure in Germany, where auditors' legal liability is limited, reducing the viability of the insurance rationale. Consistent with the reputation argument, they find that the stock prices of KPMG clients declined at the time of events that revealed KPMG's involvement in an audit failure at ComROAD. These authors also find that an unusually large number of clients dropped KPMG in 2002, the year of the ComROAD scandal.

The events at ChuoAoyama provide a powerful setting for assessing the importance of auditor reputation, allowing us to extend the findings of Weber et al. (2008). First, litigation against auditors is virtually nonexistent in Japan. This means that there is effectively no insurance role for auditing in Japan.[13] Second, the FSA's decision to suspend ChuoAoyama was unexpected and largely unprecedented.[14] Third, these events unfolded over a relatively extended period, from the first indication of accounting problems at Kanebo in Spring 2004 to early 2007, when Misuzu ceased operations. The separation in time between May 2006, when the FSA announced its suspension and PwC decided to split the firm, and its eventual demise in February 2007 allows us to clearly identify the effects of auditor reputation and separate them from the effects of the firm's closure. Fourth, we have direct evidence that reputation played an important role in these events—PwC intervened quickly and forcefully when it became clear that ChuoAoyama's problems were going to attract the attention of investors and regulators in a significant way. It seems clear that the management of PwC was prepared to sacrifice a large part of its Japanese business to preserve its reputation.[15]

---

[13] This is clearly true for Japanese firms that are not listed outside Japan but less true for Japanese firms cross-listed in the U.S. and subject to U.S. securities laws. Litigation in Japan, including securities litigation, is much less prevalent than in Western countries although this is gradually changing (Ginsburg and Hoetker 2006). In spite of an increase in litigation rates since around 1990, expected litigation costs remain lower in Japan than in the U.S. West (2001) provides evidence that the number of shareholder derivative lawsuits in Japan have increased but that settlements are unusual and stockholders lose most of these cases.

[14] Consistent with previous cases, regulators had announced that they would impose some type of sanction against ChuoAoyama. However, most previous sanctions had been relatively inconsequential.

[15] Consider the following quote from Samuel DiPiazza, then CEO of PwC: "In PwC we're not perfect, but I think we have sent the message. In Japan we shut that firm down. We gave up a major amount of businesses, but we did it because we felt that the most important [asset] was our quality in that market to be at the highest level. We feel that we have that today: even if it's smaller, it's a better quality" (*Czech Business Monthly* 2007).

The suspension of ChuoAoyama and PwC's decision to split the firm into two parts signaled to clients and investors that Aarata was of higher quality than ChuoAoyama. Such an unambiguous, firm-wide audit quality signal has not been available in prior research settings. Moreover, by suspending ChuoAoyama, Japanese regulators (perhaps inadvertently) reduced switching costs for its clients. Because firms in Japan are required to have an external auditor at all times, firms were forced to find another audit firm for the suspension period. While client firms could return to ChuoAoyama (Misuzu) when it resumed business, the appointment of interim auditors made it easier for ChuoAoyama's clients to review their contracts, given that they had already incurred some of the switching costs.

Finally, data available to us in Japan permits more detailed analysis of the auditor-switching decision than in Weber et al. (2008). First, Weber et al. (2008) cannot distinguish client switching due to supply-side effects, such as KPMG reducing its exposure to risky clients, from demand-side effects, in which clients switch to maintain a reputation for financial reporting quality. Weber et al. (2008) find that smaller firms and those that recently completed IPOs are more likely to switch auditors, but both of these characteristics are also consistent with KPMG's attempt to avoid riskier clients after the scandal. In contrast, the spin-off of Aarata meant that ChuoAoyama was already facing the loss of clients and so unlikely to reject other clients.[16] Second, we use the date of auditor changes to isolate changes that occurred after the suspension in May 2006 but before the Nikko Cordial fraud came to light in December of that year. Thus, we can more confidently associate client switching with the reputational impact of the events at ChuoAoyama. Finally, in Japan audit partners sign audit reports in their own names as well as those of their audit firms. This allows us to examine the extent to which clients follow their audit teams from one audit firm to another, which is an alternative explanation for switching that is less consistent with improving audit quality. While the audit partner names are also disclosed in Germany, Weber et al. (2008) do not use that information.

To assess the extent to which evidence from these events supports the importance of auditor reputation, we first analyze auditor changes during the period in which these events unfold. If auditor reputation is important, then we expect client firms to switch auditors when the incumbents are revealed to be of low quality. Second, we analyze the market reaction to the events that led to the FSA's suspension of ChuoAoyama. If reputation is important and we have identified these events correctly, then the costs of lower audit quality should be observable as declines in the stock prices of ChuoAoyama's clients.

III. EMPIRICAL ANALYSIS

Sample and Descriptive Statistics

We sample all firms listed on the First and Second Sections of the Tokyo Stock Exchange (TSE) in February 2008, a total of 2,199 firms. To mitigate possible survivor bias, we add firms that delisted during or after January 2004, increasing the sample by about 200 firms. We identify sample firms' auditors from Japanese securities filings (*yukoshoken hukoksho*) from fiscal 2001 through fiscal 2007.[17]

---

[16] Our understanding is that when clients started leaving, ChuoAoyama/Misuzu pursued a market share maximization approach that was also consistent with the desire to retain existing partners and staff.

[17] In Japan, most companies end the fiscal year on March 31. We use the Compustat convention to label firm/years; for example, we refer to the fiscal year ended March 31, 2007 as fiscal 2006 or F2006.

Analysis of Market Share

We report the number of publicly listed firms audited by Big and non-Big auditors in Panel A of Table 1;[18] from fiscal years 2001 through 2007 the annual average is about 2,150 firms.[19] Panel A statistics show that there is a high degree of audit market concentration in Japan. The Big auditors cover between 81 and 84 percent of the market in our sample period when measured by the number of clients and 92 to 95 percent when weighted by client firm size.

For each of the Big audit firms, Panel B of Table 1 reports the time-series distribution of the number of client firms while Panel C provides market share based on the client firm market capitalization. Panel B shows that in F2001 and F2002 four Big audit firms dominate the market. There is a shift in F2003, when Asahi (Andersen) combined with AZSA and retained the AZSA name. The numbers for F2004 are similar.

The problems at Kanebo and ChuoAoyama came to light in 2004. The problems became more serious in the middle of 2005, when government prosecutors arrested executives from Kanebo and auditors from ChuoAoyama and searched ChuoAoyama's offices. This means that any switching away from ChuoAoyama could have begun in F2005 (ending March 30, 2006). However, the number of ChuoAoyama clients stays essentially unchanged in F2005, as seen in Panel B where ChuoAoyama audited 471 clients in F2004 and 469 clients in F2005.

The suspension of ChuoAoyama and the split into Misuzu and Aarata was announced in May 2006, allowing companies to decide whether to switch auditors for F2006 before their annual stockholder meetings in June 2006. Panel B of Table 1 shows that in F2006 the total of ChuoAoyama (7 clients), Misuzu (303 clients) and Aarata (52 clients) is 107 less than the 469 clients audited by ChuoAoyama in F2005, implying that a significant number of firms moved away from ChuoAoyama as these events unfolded. The other Big audit firms were the primary beneficiaries. Because the decision to close Misuzu did not occur until February 2007, it seems reasonable to interpret the F2006 audit changes as a response to concerns about audit quality rather than changes forced by the termination of Misuzu.

The F2006 to F2007 loss of clients for Misuzu are more likely forced by its closure and, therefore, more difficult to attribute to reputational concerns. The closure was announced in late February 2007, and all but 15 of the 303 Misuzu clients in F2006 had left by F2007.[20] Misuzu terminated operations following completion of audits for F2007. To summarize, these data show that the number of publicly listed ChuoAoyama clients was essentially unchanged in F2005 but declined significantly from 469 in F2005 to 362 (i.e., 7 in ChuoAoyama, 303 in Misuzu, and 52 in Aarata) in F2006 and even further to 75 (15 in Misuzu and 60 in Aarata) in F2007. We attribute the

---

[18] We use the terminology "Big" auditors to refer to local affiliates of the large international audit networks. These are ChuoAoyama/Misuzu/Aarata (PwC), Asahi (Arthur Andersen), AZSA (KPMG), ShinNihon (Ernst & Young), and Tohmatsu (Deloitte). Non-Big auditors are all other audit firms.

[19] We limit the sample in Table 1 to observations with non-missing market capitalization data to make the sample more comparable to that used in subsequent empirical analyses. The number of observations in later tables may be lower due to the availability of data on all the control variables.

[20] The 15 client firms remaining with Misuzu in fiscal year 2007 are firms with fiscal years that end after March 31, for which the fiscal 2007 year-end concludes in calendar 2007, so that Misuzu could complete the fiscal 2007 audit before it closed on July 31 of that year. Our subsequent Table 4, Panel B provides statistics on the eventual auditor in F2007. Of the 303 firms audited by Misuzu, only 49 firms move to Non-Big audit firms. All other clients move to a Big auditor. We are unable to find the subsequent auditor for 50 firms because we are unable to find the relevant filings.

TABLE 1

Market Share Analysis of Japanese Audit Market

Panel A: Distribution of Clients across Time

Fiscal Year	Big Auditor	Big Auditor Percent by Number of Clients	Big Auditor Percent by Size of Client	Non-Big Auditor	Non-Big Auditor Percent by Number of Clients	Non-Big Auditor Percent by Size of Client	All Audit Firms
F2001	1,565	81.2%	93.6%	363	18.8%	6.4%	1,928
F2002	1,757	82.0%	93.4%	386	18.0%	6.6%	2,143

In Panel A Big Auditor refers to the following audit firms, with their affiliations to worldwide audit networks in parentheses: ChuoAoyama/Misuzu/Aarata (PwC), Asahi (Andersen), AZSA (KPMG), ShinNihon (Ernst & Young), and Tohmatsu (Deloitte). Non-Big Auditor refers to all other audit firms. Size of client is measured by market capitalization at the end of the fiscal year. The count of companies in all panels includes only those firms for which market capitalization data are available.
Panel D presents the auditor turnover rate for the sample firms. Change of auditor from ChuoAoyama to Misuzu or Aarata is not counted as an auditor change. Big Auditor refers to local affiliates of the large international audit networks. These are ChuoAoyama/Misuzu/Aarata (PwC), Asahi (Arthur Andersen), AZSA (KPMG), ShinNihon (Ernst & Young), and Tohmatsu (Deloitte). Non-Big Auditor refers to all other audit firms in Japan.

Panel E presents the number of ChuoAoyama clients that switched during each month in 2006 and 2007 to their final choice of auditor, which we define as the auditor for fiscal year 2007. The sample in Column A is all clients that leave ChuoAoyama and do not revert to Misuzu. Column B consists of clients that reverted to Misuzu but hired an interim auditor during the suspension. Column C is the sample of ChuoAoyama clients that reverted to Misuzu but had no interim auditor during the suspension period. Column D is all ChuoAoyama clients, i.e., the sum of columns A, B, and C.

movement away from ChuoAoyama from F2005 to F2006 to concerns about audit quality, supporting the importance of reputation effects.[21]

By F2007, when the auditor changes forced by the termination of Misuzu had largely occurred, the market share of the remaining Big auditors was 81.2 percent (Panel A of Table 1), only marginally below the level of 83.8 percent in F2005. The size-weighted shares reported in Panel C of Table 1 show that the market share of Big auditors is even more pronounced. Non-Big auditors capture their highest share of the market in F2007 at only 7.6 percent.

Panel D of Table 1 reports the auditor turnover rates in Japan for the sample time period. In all six years of the sample period auditor turnover rate for the Big auditors excluding ChuoAoyama and Misuzu in Japan is low, ranging from 0.6 percent in F2004 to 2.5 percent in F2003, with most years around 1 percent. The turnover rate for non-Big auditors is higher, ranging from 3.1 to 10.7 percent. The turnover rate for ChuoAoyama through fiscal 2005 is similar to that of the other Big audit firms. However, turnover for ChuoAoyama increases substantially to 23.7 percent in fiscal 2006, consistent with Panels B and C. This suggests there is a shift away from ChuoAoyama as its problems became more evident. Turnover rate for ChuoAoyama/Misuzu in F2007 is much higher again, at 92.5 percent, but this is due to the winding up of the firm.

The decision to terminate Misuzu followed the Nikko Cordial scandal, which was first revealed in December 2006, seven months after the suspension order against ChuoAoyama in May 2006. There is no indication that the closure of Misuzu was anticipated before the Nikko Cordial became public. Supporting this, there are no client departures from Misuzu between the end of the suspension on September 1, 2006 and December 17, 2006 when the Nikko Cordial scandal became public. Table 1, Panel E provides further information on the timing of auditor switches. We are able to find the exact auditor change announcement for 453 of the 469 ChuoAoyama clients identified in Table 1, Panel B. Table 1, Panel E shows that client switching after the suspension occurs in May, June, and July of 2006. The only departure during December occurs late in the month, after the Nikko Cordial announcement. The next major batch of departures occurs in May 2007, after Misuzu announced its impending closure in February 2007. This suggests that the earlier departures from ChuoAoyama were *not* due to fears that the firm would cease operations after the suspension announcement in May 2006.

To test whether the F2006 auditor switches away from ChuoAoyama are unusually frequent, we estimate a logit model of factors that explain auditor changes. The control variables are drawn from previous research on auditor switches and include firm size (log of total assets), growth (percentage change in total assets), leverage, change in leverage, profitability (ROA), a loss dummy, U.S. listing, *keiretsu* inclination, auditor industry expertise, earnings quality as measured by accruals, whether the firm completed an M&A transaction in the preceding two years, and industry fixed effects.[22] We provide details of data sources and variable definitions in Appendix B. The *keiretsu* inclination variable measures whether and to what extent these firms are part of the large corporate groups common in Japan (e.g., Aoki et al. 1994; Hoshi and Kashyap 2001).

We include dummy variables for whether the client is a ChuoAoyama client (*CA*), for fiscal year 2006 (*F2006*), and for the interaction of these two dummies (*CA_F2006*). The interaction variable is our primary interest because it measures the extent to which client firms switch away from ChuoAoyama in fiscal 2006, the period in which we argue that auditor reputation drives switching.[23]

---

[21] To provide qualitative evidence on the reasons provided by clients for leaving ChuoAoyama, we examined the auditor change disclosure filed by these companies after the suspension announcement. The filing document known as *konin kaikeishi tou no idou* (change (transfer) of certified public accountant) is obtained from the TSE Timely Disclosure Network (TDnet). In a random sample of 40 companies that we examined, companies either offered no reason for the change or boilerplate language that the change was due to the suspension. We concluded that this disclosure is not useful for our analysis.

[22] For example, see DeFond (1992), Francis and Wilson (1988), Barton (2005), Weber et al. (2008), and Landsman et al. (2009).

We report the results of these regressions in Table 2. There are fewer observations in the multivariate tests in Table 2 than in Table 1 because we require data on all of the control variables.[24] In the Column (1) estimation we do not treat a move from ChuoAoyama to Aarata as a change, while in the Column (2) estimation we do treat these observations as changes.

The estimate on *CA_F2006* indicates that the likelihood of an auditor change is higher in fiscal 2006 when ChuoAoyama was the incumbent auditor. We report both the regular logit marginal effect and the Ai and Norton (2003) marginal effect estimate for this variable. In the first specification, the Ai and Norton marginal effect on *CA_FY2006* is 0.23 with an associated Z-statistic of 6.72 after applying the Ai and Norton (2003) and Norton et al. (2004) methodology. This implies, other variables held at their means, that a ChuoAoyama client is 23 percent more likely to switch auditors in fiscal year 2006, an effect that we attribute to reputation. The associated main effects show that ChuoAoyama client firms are, in general, less likely to switch away from ChuoAoyama than from other audit firms (marginal effect −0.01), but more likely to switch in F2006 (marginal effect of 0.01) than in other years. These effects are, however, smaller and less significant than that for the interaction variable.

The results for the interaction term become stronger in the Column (2) specification in Table 2, where we treat moves to Aarata as auditor changes, with the Ai and Norton marginal effect of 0.34 (Z-statistic = 8.52). These results support the notion that there was an unusually high likelihood of switching away from ChuoAoyama in F2006, when doubts about the quality of that firm's audit practice manifested themselves in a significant way.

Determinants of Auditor Switching for Former ChuoAoyama Clients

We next examine the determinants of the choice to switch auditors to investigate our prediction that audit quality drives these switches. To do this, we use actual dates of the auditor changes to classify the 469 publicly listed ChuoAoyama clients in fiscal 2005 into three groups based on their auditor choices for fiscal 2006. The three principal groups are:[25]

1. 99 firms that did not use an interim auditor during the suspension and reverted to ChuoAoyama/Misuzu at the end of the suspension on September 1.
2. 199 firms that used an interim auditor for the period of the suspension and reverted to ChuoAoyama/Misuzu at the end of the suspension.
3. 155 firms that appointed a new auditor before the suspension began and continued to use that auditor after the suspension ended.

We view these choices as implying different relative levels of concern for audit quality. Firms in group (1) return to ChuoAoyama (Misuzu) after the suspension without using an interim auditor.

---

[23] Because the conventional logit coefficients on interaction variables do not provide a statistical test of whether the economic interaction of interest is statistically significant (Ai and Norton 2003; Norton et al. 2004; Greene 2009), we provide the estimated mean marginal effect for this variable along with the corresponding Z-statistic at the bottom of Table 2. We examined, but do not report, the graphical analyses suggested by these authors that plots the estimated interaction effects for various levels of the predicted probabilities. The interaction effect for *CA_F2006* dummy is positive and statistically significant for all relevant levels of the predicted probability. These graphs are available upon request.

[24] We exclude the changes away from ChuoAoyama/Misuzu after fiscal 2006 because these switches are likely forced by the decision to shut down Misuzu... Note that the sample size in Column (2) is lower than in Column (1) because when we exclude the 52 Aarata observations as an auditor change, one of the industry fixed effects drops out because there is no variation in auditor change in that industry.

[25] Of the remaining 16 firms, nine had previously used two auditors and dropped ChuoAoyama during the suspension, and seven firms lack the requisite data.

AuditorChange takes the value 1 when the auditor in the next fiscal year is not the same as in the current fiscal year. Data are from fiscal year 2001 to fiscal year 2006 (inclusive). Auditor change from ChuoAoyama to Misuzu is not counted as a change. Change from ChuoAoyama to Aarata is not considered a change in Column (1) and is counted as a change in Column (2). Z-statistics are based on robust standard errors. Marginal effects are computed at the means of the independent variables except for dummy variables, where it is the change in value from 0 to 1. The Ai and Norton marginal effects and Z-statistics on the interaction term are calculated following Norton et al. (2004).

All other variables are defined in Appendix B.

Variable Definitions:

$AuditorChange_t = 1$ if the audit firm changes from year t–1, 0 otherwise;

CA = 1 if ChuoAoyama is the prior year audit firm, 0 otherwise;

F2006 = 1 if fiscal year is 2006, 0 otherwise;

CA_F2006 = 1 if ChuoAoyama is the audit firm in F2005 and the year is F2006, 0 otherwise;

$\%\Delta TotalAssets_t$ = percentage change in total assets from year t–1; and

$\Delta Leverage_t$ = change in leverage from year t–1.

These firms operated for two months without an external auditor and therefore were apparently relatively less concerned about audit quality. As discussed earlier and in footnote 11, regulators in Japan did not strictly enforce the requirement that firms need to have an external auditor at all times likely due to the supply disruption caused in the audit industry due to the ChuoAoyama suspension. Firms in group (2) return to ChuoAoyama/Misuzu after using an interim auditor for the period of the suspension. The use of an interim auditor indicates that the firm has the ability to comply with regulations and market expectations relating to audit quality, thus signaling the demand for higher-audit quality than the first group of firms, although our results continue to hold if we combine groups (1) and (2).

The third category is composed of 155 firms that switch to a new auditor for fiscal 2006, including the 145 firms that switch after the suspension was announced and the ten firms that switch before that time. Considering the substantial costs to switch auditors, the firms in this group likely value audit quality most highly relative to firms in the other two groups.

We consider the auditor switches to Aarata as changes that enhanced audit quality for a few reasons.[26] First, its key management and most staff came from Aoyama, which was seen to have higher-audit quality than Chuo, a judgment that interviewees repeatedly made to us. Second, its clients came disproportionately from Aoyama. Of the 52 former ChuoAoyama clients that shifted to Aarata at its inception on July 1, 2006, 14 had been clients of Aoyama (the Price Waterhouse affiliate) prior to the April 2000 merger of Chuo and Aoyama, 11 were previously clients of Chuo (the Coopers & Lybrand affiliate), while 18 were previously clients of other firms (data are unavailable for the remaining nine firms). Aarata took a much larger fraction of former Aoyama clients than it did former Chuo clients, consistent with information we gathered in our interviews that Aarata was staffed principally by former Aoyama personnel.[27] Because Chuo was substantially larger than Aoyama, the numbers above imply that the majority of former Aoyama clients still with ChuoAoyama in fiscal 2005 (14 of 23 firms, or 60.9 percent) moved to Aarata. Only a small fraction (11 of 307 firms, or 3.6 percent) of former Chuo clients still with ChuoAoyama in fiscal 2005 moved to Aarata.

To investigate the auditor choice more formally, we fit an ordered logit model of these firms' auditor decisions for fiscal 2006. Using the groups described above, the dependent variable *Switching* is set to 0 for firms that went back to ChuoAoyama/Misuzu without using an interim auditor, 1 for firms that went back to ChuoAoyama/Misuzu after using an interim auditor, and 2 for firms that switched away from ChuoAoyama/Misuzu. The signal of the importance of audit quality conveyed by the above choices makes the dependent variable *Switching* an ordinal ranking of audit quality. Table 3 presents the results of this estimation. In the first estimation in Column (1) of Table 3 we drop all Aarata clients and in the second estimation in Column (2) we set the dependent variable to 2 for firms that moved to Aarata (a higher-quality audit alternative).

---

[26] In a May 10, 2006 press release PwC announced the formation of a new firm, Aarata, that "will adopt international best practices . . . will meet high standards of audit quality . . . [and have a] high level of oversight by PwC." Further, DiPiazza, then PwC's CEO, stated that Aarata's limited size reflected the availability of staff who met the firm's performance standards. Finally, when announcing Misuzu's closure on February 20, 2007, DiPiazza stated: "We would have hoped the Japanese profession evolved to a higher level of quality over the years. It did not. Cultural differences cannot be used as an excuse for lower quality" (*Financial Times* 2007). See also footnotes 2 and 13.

[27] There are at least three non-mutually exclusive explanations for the way clients switched to Aarata: (1) PwC encouraged some firms to move to Aarata to maintain the relationship given the size and visibility of these clients (e.g., Sony, Toyota, non-Japanese multinationals such as Unilever); (2) firms that were originally clients of Aoyama followed their external audit team to Aarata; (3) firms for which audit quality is especially important, perhaps because of their size/visibility or links overseas (foreign sales, investors, listings, or some combination thereof), made the switch due to audit-quality concerns. These explanations are all consistent with these firms valuing audit quality relatively highly.

TABLE 3

Ordered Logit Estimation of the Likelihood that ChuoAoyama Clients during the Period of Suspension: (1) Do Not Report an Interim Auditor, (2) Switch to an Interim Auditor and Then Revert to Misuzu, or (3) Switch to a Final Audit Firm (do not revert back to Misuzu after suspension ends)

*, **, *** Represent significance at the 10 percent, 5 percent, and 1 percent levels, respectively, (two-sided tests).
The dependent variable, *Switching*, takes the value of 0 if the firm does not have any interim auditor during the suspension, 1 if it adopts an interim auditor and goes back to Misuzu after the suspension ends, and 2 if it adopts a final auditor and does not revert to Misuzu. Column (1) excludes companies that move to Aarata as the final auditor after the suspension, whereas Column (2) includes companies that move to Aarata. All independent variables are measured for fiscal year 2005. Robust Z-statistics are reported. The "Odds Change" column presents the value of the change in odds for one standard deviation change in the value of the independent variable measured as exp(b∗SD of X), i.e., the change in odds for a one standard deviation increase in X.

For the estimation in Table 3 we use largely the same set of independent variables as in Table 2 and add additional variables that we collected for the ChuoAoyama sample to capture cross-sectional variation in the demand for audit quality. All variables are defined in Appendix B. We include firm size (*Log Total Assets*), risk (*Std Dev Returns*), and firm complexity (*Number of Segments*) as larger, riskier, and more complex firms need higher-quality audit effort. Firms with greater growth options (*Market-to-Book*) are likely to have greater information asymmetry between management and investors and, hence, are likely to demand higher-audit quality. *Leverage* is included to assess demand for high-quality auditing from debt holders. Firms with better performance as measured by *ROA* and *Annual Returns* may have lower demand for high-audit quality. However, Landsman et al. (2009) find that firms with poor performance are more likely to change auditors.

We include three variables that measure the extent of foreign interaction of the clients to test if non-Japanese investors and stakeholders drive demand for higher-quality auditing. These variables are *Foreign Ownership*, *Overseas Sales Ratio*, and *US Listing*. We expect firms belonging to a Keiretsu (*Keiretsu Inclination*) and those with a dominant owner-manager (*Owner Manager*) to have a lower likelihood of switching from ChuoAoyama since concentrated owners are an alternate monitoring channel that is a substitute for high-quality auditing. On the other hand, greater agency costs present in these ownership structures between the different classes of owners (concentrated versus public shareholders) might drive a demand for higher-audit quality.

Clients may be reluctant to switch auditors if ChuoAoyama were the industry expert auditor, so we add *Industry Expert Auditor* as a determinant of the switching decision. Landsman et al. (2009) suggest that firms with high accruals entail greater audit risk, suggesting a need for higher-quality audits; hence, we include a measure of absolute discretionary accruals (*Abs Disc Accrual*). Similarly, firms that recently complete a merger or acquisition (*M&A*) also entail greater audit risk, suggesting need for higher-quality auditors. We include the stock returns on the suspension announcement date (*Suspension Announcement Return*) to examine if companies that suffered a more negative market reaction would be more likely to leave ChuoAoyama. Finally, industry fixed effects allow for possible systematic differences at the industry level.

We report the results of these regressions in Table 3. In both estimations, *Log Total Assets* and *Market-to-Book* are both positively related to *Switching* at significance levels of 5 percent or less.[28] This shows that larger firms and growth firms are more likely to move from ChuoAoyama to higher-quality auditors. These effects are economically significant—a one standard deviation increase in firm size leads to a 55 percent (69 percent) increase in the switching likelihood in Column (1) (Column (2)), as seen in the changes in the odds ratios presented in the table. A similar change in market-to-book ratio leads to a change of 46 percent (37 percent) in Column (1) (Column (2)). In both estimations, we find a reliably negative coefficient on *Owner Manager* defined as firms where the President or Chairman are among the top 10 shareholders, implying that firms with a dominant manager-shareholder, reflecting potential managerial entrenchment, are less likely to be concerned about audit quality. As an alternative to the entrenchment explanation, owner-managers could be less concerned about audit quality if they serve as a substitute monitoring mechanism, lowering investor demand for auditing. No other variables are consistently significant.[29] To the extent that client firm size, market-to-book, and owner management are associated with a demand for higher-audit quality, these results support our hypothesis that the auditor changes are explained by differential demands for audit quality. However, we do not observe a similar effect for measures of risk and firm complexity.

As a robustness check, we test an alternate logit specification for which we define firms that reverted to Misuzu as one group irrespective of whether they hired an interim auditor, with the dependent variable taking the value 0 for clients that reverted to Misuzu and 1 if they switched auditors. Results (not tabulated) are similar to the ordered logit results. Size, market-to-book, and owner-manager continue to be significant with the same signs. In addition, firm complexity as

---

[28] We also estimated ordered logit models where the dependent variable is coded as 0 for firms that revert to Misuzu after the suspension, 1 for firms that switched to Aarata, and 2 for firms that switched to a firm other than Aarata (non-PwC). Results are similar to those reported here.

[29] In Column (1) companies with lower accounting quality as measured by absolute value to total discretionary accruals are more likely to switch auditors, suggesting that clients with potentially higher audit risk (Landsman et al. 2009) preferred to switch to a higher-quality auditor.

measured by number of segments becomes statistically significant, suggesting that more complex firms exhibit demand for higher-quality auditing.

Also consistent with the above results, Aarata's clients were two to three times larger based on total assets, sales, or market capitalization than those that stayed with Misuzu and 50 to 100 percent larger than those that moved to other audit firms. Aarata's clients also have higher levels of foreign ownership, overseas sales, and U.S. listings.

Finally, because it is unlikely that ChuoAoyama rejected larger clients in the aftermath of its suspension, our results are consistent with a demand-side effect in which client firms drive switching decisions. This contrasts with the results in Weber et al. (2008), who find that smaller firms and those with recent IPOs switched auditors, a result that is also consistent with a supply-side effect in which KPMG rejected smaller clients to reduce audit risk.

Client Switching and Audit Personnel Moves

We attribute the changes away from ChuoAoyama in 2006 to a decline in ChuoAoyama's audit quality. An alternative interpretation is that audit clients simply followed their audit teams from one audit firm to another. Blouin et al. (2007) provide evidence that a significant number of Andersen clients followed their audit teams to new audit firms following Andersen's demise in 2002 to minimize switching costs. Given the closeness of relationships between auditors and clients in Japan, we expect this to be an important phenomenon in Japan as well. On the other hand, if the goal of changing auditors is to improve quality, then it is likely that clients would require a different audit team.

In Japan, audit reports are signed by individual audit partners, which allows us to identify the partner(s) responsible for the audits. We report the results of analyzing the auditor signatory data in Table 4. In Panel A, for the set of client firms that switch away from ChuoAoyama between F2005 and F2006, including those that went to Misuzu and Aarata, we report data on the audit partner(s) who signed these firms' audit reports in fiscal 2005 on behalf of ChuoAoyama and then in fiscal 2006 on behalf of the new audit firm. We then classify the firm as either having at least one common signatory across years—which we interpret as implying the same audit team at the new firm—or not.[30] The results show that there was a strong tendency for clients that stayed with PwC, at either Misuzu or Aarata, to have at least one common signatory, consistent with these audit firms having been formed from ChuoAoyama. Of the 50 Aarata clients that came from ChuoAoyama, 38 (76 percent) had signatories in common; of the 281 Misuzu clients, 239 (85 percent) had signatories in common. In strong contrast, none of the other switches had signatories in common with the fiscal 2005 ChuoAoyama auditors. The data thus clearly reject the interpretation that switches away from ChuoAoyama in fiscal 2006 were due to clients following their audit teams to new audit firms.

In Panel B of Table 4 we repeat the analysis for firms with signatory data available for fiscal years 2005 and 2007. The results are very different for these auditor changes. Here we find significant overlap in signatories for all the fiscal 2007 audit firms: 54 percent for Aarata, 35 percent for AZSA, 53 percent for ShinNihon, 27 percent for Tohmatsu, and 27 percent for other audit firms collectively.[31] This is due to the movement of audit teams from Misuzu to

---

[30] In a given year, firms typically have one, two, or three auditor partners sign the report. Japan has mandatory auditor rotation (of audit partners within firms) so we do not expect these percentages to equal 100 percent even when there is no turnover.

[31] The number of firms in Table 4, Panel A differs from that in Panel B due to data constraints, either because we do not find the relevant filing or because some firms delist between fiscal years 2006 and 2007.

TABLE 4

The Relation between Audit Signatories at ChuoAoyama in Fiscal Year 2005 and Those at Subsequent Audit Firms in Fiscal Years 2006 and 2007

Panel A: Continuation of at Least One Audit Partner from ChuoAoyama to the Successor Audit Firm between Fiscal Years 2006 and 2005

	Same Partner in Next Audit Firm as in ChuoAoyama				
Successor Audit Firm	**No Common Signatory**	**Percent of Total**	**At Least One Common Signatory**	**Percent of Total**	**Total**
Aarata	12	24%	38	76%	50
AZSA	29	100%	0	0%	29
Misuzu	42	15%	239	85%	281
Shin Nihon	37	100%	0	0%	37
Tohmatsu	23	100%	0	0%	23
Other Auditors	19	100%	0	0%	19
Total	162	37%	277	63%	439

Panel B: Continuation of At Least One Audit Partner from ChuoAoyama to the Successor Audit Firm between Fiscal Years 2007 and 2005

	Same Partner in Next Audit Firm as in ChuoAoyama				
Successor Audit Firm	**No Common Signatory**	**Percent of Total**	**At Least One Common Signatory**	**Percent of Total**	**Total**
Aarata	25	46%	29	54%	54
AZSA	53	65%	29	35%	82
Misuzu	0	0%	7	100%	7
Shin Nihon	77	47%	88	53%	165
Tohmatsu	45	73%	17	27%	62
Other Auditors	36	73%	13	27%	49
Total	236	56%	183	44%	419

The table provides descriptive statistics on how many ChuoAoyama clients were audited in fiscal years 2006 or 2007 by the same audit partners in the successor audit firms as the audit partner who audited them in ChuoAoyama in fiscal year 2005. Audit partners are the signatories to the auditor report. For companies with multiple signatories, any one of the signatories being present in the next audit firm is counted as a common audit partner. The number of firms in Panel A differs from that in Panel B due to data availability, either because we do not find the relevant filing or because some firms delist between fiscal years 2006 and 2007.

other firms, consistent with the process we describe above for the winding up of Misuzu, under which audit team/client pairings tended to move to new audit firms together. It also reinforces our conclusion that the changes from fiscal years 2006 to 2007 are systematically different from those in fiscal years 2005 to 2006.

Event Study Analysis

Following previous research, we next analyze the market reaction to events associated with downward changes in the market's beliefs about an auditor's quality (e.g., Menon and Williams 1994; Baber et al. 1995; Chaney and Philipich 2002; Weber et al. 2008). Because there is no significant litigation risk for auditors in Japan, any abnormally negative returns to ChuoAoyama clients at the time of these events are likely due to either changes in expectations about audit quality or switching costs, although switching was not forced at the time of these events. To identify relevant events, we search Factiva for media articles related to the Kanebo fraud or otherwise discussing ChuoAoyama, Misuzu, or Aarata during the period outlined in Section II. Important events are listed in Appendix A.[32]

Table 5, Panel A provides mean and median market-adjusted returns for the three-day window centered on the event dates in Appendix A. Events 2, 4, 7, 9, 10, and 11 exhibit a statistically significant negative mean and median market reaction although the magnitudes are generally quite modest. The exception is event 9 with a mean return of −2.56 percent when PwC sent auditors from the U.S. and U.K. to address the problems at ChuoAoyama. Surprisingly, events 1 and 5 exhibit a small positive mean reaction. Following previous research, to address cross-sectional correlation among the contemporaneous daily stock returns of the ChuoAoyama client firms, we form a portfolio of these firms and estimate an adjusted market model regression using the time-series of portfolio returns.[33] Specifically, we estimate:

$$Return_t = \alpha_0 + \beta_1 Return_{TSEINDEX,t} + \theta_k Event_{k,t} + \varepsilon_t \tag{1}$$

where $Return_t$ is the return on day t to an equal-weighted portfolio of ChuoAoyama client firms, $Return_{TSEINDEX,t}$ is the return on the TSE Topix index for day t, and $Event_{k,t}$ is a dummy variable equal to 1 during the three-trading-day window centered on each of the 11 events, $k = 1,\ldots,11$. We estimate the regression over the 798 trading days from January 1, 2004 through March 31, 2007, which includes the full set of events.

We estimate Equation (1) for each of the events individually as well as for the combined set of events, and report results in Table 5, Panel B. The results provide little evidence of any significant effect on most event dates. The coefficients on the event dummies are small and insignificant for 10 of the 11 events. Consistent with the univariate results, the only exception is event 9, which shows a return of −0.88 percent (t = −3.56). When we combine the events, the coefficient on the overall event dummy is −0.15 percent (t = −1.94). This evidence offers modest support, at best, for the reputation argument. We also tested robustness of these results for a shorter window of time from June 1, 2004 to May 21, 2006 with 492 trading days and obtained similar results.

---

[32] We validate our set of events by comparing the dates to those in three other studies by Japanese authors. See Sakuma (2009), Numata and Takeda (2010), Saito and Takeda (2011). We find substantial overlap in the dates, which provides assurance that we have identified the important events. These studies do not overlap with our work except in our event study analysis.

[33] We follow an approach similar to the multivariate regression model (MVRM) used previously by Schipper and Thompson (1983) and Bernard (1987). Under this approach, which Schipper and Thompson (1983; hereafter, ST) refer to as the joint GLS estimator, the time-series of individual firms' returns is used to compute return cross-correlations. That is, the portfolio of returns is a weighted average of all the returns, where the weights are calculated based on the inverse of the variance-covariance matrix estimated from firm-by-firm regressions. To be effective, this procedure requires a large number of time-series observations relative to the number of sample firms (Bernard 1987, 6). Because we have a relatively large number of firms compared to the number of time-series observations, we use a variant of the joint GLS approach also used by ST where we use unweighted averages of the firm-level returns, which assumes that the true covariance matrix is a scalar times the identity matrix. When we estimate the Table 5 regression specifications using the joint GLS estimator, the overall return is −0.06 percent (t = −2.00).

*, **, *** Indicate that the returns are significantly different from 0 at the 10 percent, 5 percent, and 1 percent levels of significance, respectively.

Panel A presents the mean and median market-adjusted returns for ChuoAoyama clients over the three-day window centered on the event dates tabulated in Appendix A. Market adjustment is done using TSE Index for the market index. All returns are in percents.

Panel B presents the coefficients and t-statistics (in parentheses) of the following regression. The event dates are presented in Appendix A and the variable definitions and data sources in Appendix B. TSE Index returns are computed using the Tokyo Stock Price Index (TOPIX). The sample size of 798 comes from returns on all trading days between January 1, 2004 and March 31, 2007.

If the reputation argument matters more for larger, more prominent firms in Japan, then we might expect the event date results to be stronger for clients listed on the First Section TSE (larger, more prominent firms).[34] These results (not tabulated) are similar to those we report in Table 5, with an overall return of −0.15 percent (t = −2.09).[35] Overall, there is little evidence that any of these events is associated with economically significant abnormal event performance.

To summarize, the event study results provide little evidence that the former clients of ChuoAoyama suffered any material decline in value on the dates that we identify. Numata and Takeda (2010) also conduct market reaction tests on the ChuoAoyama event dates. That paper includes four of our event dates—events 2, 3, 4, and 11—and does not follow the Schipper and Thompson (1983) approach to the event study, instead carrying out a market model test for a sample of only First Section companies. They report results similar in magnitude and significance to our results in Panel A of Table 5 and conclude that the significant negative reaction indicates a reputational penalty. However, the multivariate regression approach following Schipper and Thompson (1983) and our larger set of dates weakens the estimates in our tests. Our results are in contrast to those in Weber et al. (2008), who find a statistically significant negative return for two out of their three event dates and for the combination of event dates. However, it is difficult to reach very strong conclusions based on this evidence, given the relatively long time period over which concerns about ChuoAoyama's low audit quality were revealed. It could also be that these events had negative implications not only for ChuoAoyama clients, but also for firms, in general, in Japan, especially those on the TSE First Section, so that market-adjusting the returns removes the effect we are looking for.[36]

IV. SUMMARY AND CONCLUSIONS

In May 2006, the Japanese FSA took the unprecedented step of suspending the operations of ChuoAoyama, the PwC affiliate in Japan, for two months for its role in a major accounting fraud at Kanebo. Even as the suspension was announced, PwC was taking its own actions to remedy the apparent shortcomings of its Japanese unit. First, it brought in high-level personnel from overseas to revamp ChuoAoyama's audit operations in an attempt to improve audit quality. Second, it set up a new, smaller Japanese affiliate, PwC Aarata, which was positioned as a high-quality audit firm. PwC used this firm to audit important Japanese clients like Toyota and Sony, as well as the Japanese operations of large multinational clients such as Unilever. Third, when another major fraud came to light after ChuoAoyama resumed business as Misuzu, PwC shut down Misuzu, ceding a large part of its Japanese business to competitors. These actions make it clear that PwC viewed the audit-quality issues at ChuoAoyama as potentially damaging to its international reputation, and support our view that an auditor's reputation for quality is of first-order importance.

---

[34] As another robustness check, we also examine the raw and market-adjusted returns for these firms in short windows around each of these events, as well as for the subset listed on the First Section of the TSE. The market-adjusted returns to some of these events are significantly negative and significantly more negative than those for the non-ChuoAoyama clients. The magnitudes of these abnormal returns and the differences in abnormal returns, however, are quite small. These results are somewhat stronger when we restrict attention to stocks listed on the TSE First Section. Perhaps the strongest evidence in favor of an effect is the mean negative raw (market-adjusted) return of −3.14 percent (−0.64 percent) for First Section ChuoAoyama clients over a three-day window centered on the FSA suspension announcement (event 11), although the corresponding mean returns for non-ChuoAoyama clients are also negative, at −2.59 percent (−0.10 percent). While statistically significant, differences between these amounts are small in economic magnitude.

[35] As a further robustness check, we also perform these tests using returns for a portfolio of all non-PwC clients in our sample as the benchmark rather than the market index returns (not reported in tables). There is, again, little evidence of systematically negative returns, with an overall return of −0.03 percent (t = −1.48).

[36] For First Section TSE stocks the mean raw return for the ChuoAoyama clients on the suspension announcement date is −3.14 percent and for other TSE stocks is −2.59 percent, which is some evidence of this possibility.

We use these events to provide evidence on the importance of an auditor's reputation for quality. Previous studies using U.S. data have difficulty distinguishing the relative importance of an auditor's market-driven incentive to maintain a reputation for delivering quality audits versus the possibility that auditors are subject to potentially large, even catastrophic, legal liability for defective audits. Because litigation concerns are negligible in Japan, the litigation argument can be effectively ruled out. Consequently, we focus on whether these events provide evidence that supports the importance of auditor reputation.

Our results are largely consistent with the importance of reputation effects. We find evidence that a relatively large number of ChuoAoyama's clients left the firm for other auditors as the seriousness of ChuoAoyama's quality problems became evident. The rate of client turnover at ChuoAoyama in fiscal year 2006, before it became apparent that the firm would be shut down but after audit-quality questions had been raised, was substantially higher than would otherwise be expected, consistent with clients leaving once the firm's reputation for quality was seriously diminished. Moreover, we find that the likelihood of switching is higher for larger clients and clients with higher market-to-book ratios, characteristics associated with a demand for higher-audit quality, and lower for firms with greater managerial ownership, indicating a lower demand for audit quality in such firms. Clients that moved to Aarata were also larger, with higher market-to-book ratios, a greater extent of cross-listing, and higher foreign ownership. These switches are not the result of clients following their audit teams to new auditors. Our event study results weakly support the auditor-quality argument, but are likely to lack power because questions about ChuoAoyama's audit quality were revealed over an extended period.

Our conclusions are subject to two caveats. First, we find that clients switched away from ChuoAoyama in large numbers in Spring 2006, just after Japanese regulators announced the two-month suspension and PwC formed Aarata. While we interpret these events as being a clear and undeniable signal of audit-quality problems at ChuoAoyama, we cannot know for sure what drove these switches. It is possible that the suspension caused firms to switch auditors for reasons unrelated to audit quality. Second, our analysis presumes that audit quality is important to Japanese companies. While we believe this to be the case, especially over the past two decades as Japanese capital markets have evolved to be more like their Western counterparts, it is possible that audit quality is, in general, less important in Japan.

APPENDIX A

Significant Events in the Kanebo/ChuoAoyama Scandal, Including Events Used in Event Study Analysis

	Date	Event
Event 1	07/09/2004	Kanebo drops ChuoAoyama as auditor
Event 2	10/28/2004	Kanebo reports that the preliminary internal investigation has found fraud. Investigation continues.
	03/31/2005	End of Fiscal 2004
Event 3	04/13/2005	Results of fraud investigation announced by Kanebo. Will restate last five years of financial statements.
Event 4	07/29/2005	Three former Kanebo executives are arrested. CA offices are searched.
Event 5	08/18/2005	Indictments brought against ChuoAoyama auditors.
Event 6	09/13/2005	Four auditors from CA who audited Kanebo are arrested.
Event 7	09/19/2005	Top executives from CA are questioned by prosecutors.
Event 8	10/03/2005	CA partners step down. Three CA auditors indicted. FSA indicates it will impose penalties on CA.
Event 9	02/20/2006	PwC sends team of auditors from U.K. and U.S. to revamp ChuoAoyama.
Event 10	03/30/2006	ChuoAoyama accountants plead guilty to falsifying Kanebo financials.
	03/31/2006	End of Fiscal 2005
Event 11	05/10/2006	CA suspension announced; PwC announces two-firm formula with creation of a new, higher quality firm.
	03/31/2007	End of Fiscal 2006

APPENDIX B

Variable Definitions

Variable Name	Definition	Source
Switching	Ordinal ranking of audit quality that takes the value 0 for firms that went back to ChuoAoyama/Misuzu after the suspension without using an interim auditor, 1 for firms that went back to ChuoAoyama/Misuzu after using an interim auditor, and 2 for firms that switched away from ChuoAoyama/Misuzu.	Company Filings
Market Cap	Market value of equity in USD millions.	Worldscope
Total Assets	Total assets in USD millions.	Worldscope
Log Total Assets	Natural log of total assets.	Worldscope
Market-to-Book	Market value of equity/book value of equity.	Worldscope
Leverage	Long-term debt divided by total assets.	Worldscope
Net Income	Net Income in USD millions.	Worldscope
ROA	Net income divided by total assets.	Worldscope
Loss	Indicator variable that takes the value 1 if net income is less than 0, and 0 otherwise.	
Annual Returns	Fiscal year stock returns.	Datastream
Foreign Ownership	Percent ownership of the firm's equity by foreign entities.	JCH, 2004
Overseas Sales Ratio	Ratio of sales outside Japan to total sales, expressed in percentage.	JCH, 2004
Number of Segments	Number of distinct divisions for which shares of total sales are reported.	JCH, 2004
Firm Age	Years since the firm was founded.	JCH, 2004
US Listing	All U.S. listings, including those via stock exchange, portal, and the OTC.	Citibank ADR database
Std Dev Returns	Firm-level standard deviation of daily stock returns in 2005.	Datastream
Industry	Industry affiliation of the company.	Tokyo Stock Exchange
TSE Index	The Tokyo Stock Price Index (TOPIX) is a composite index of all common stocks listed on the first section of the Tokyo Stock Exchange.	Datastream
Keiretsu Inclination	*Keiretsu Inclination* measures the closeness to the *keiretsu*, with higher numbers indicating a closer inclination. There are two types of *keiretsu*, horizontal (also known as "main bank groups") and vertical; for horizontals, the data are from Part III of the book, and for verticals, from Part II. The most recent edition of the source (2001) provides information as of 2000. This variable ranges from 0 for companies that are not part of a *keiretsu* to 4 for companies with the highest level of inclination ("nucleus" group companies). The measured inclination is based on five factors: (1) the characteristics and historical background of the groups and/or the company; (2) sources and amount of bank loans; (3) board of directors sent by and/or sent to nucleus and/or other group companies; (4) the company attitude toward the group; and (5) the company's connections with other groups and/or non-group companies.	Industrial Groupings in Japan

(continued on next page)

APPENDIX B (continued)

Variable Name	Definition	Source
Audit Fees	Audit fees paid to ChuoAoyama for FY 2005 in USD millions.	Company filings
Owner Manager	Indicator variable that takes the value 1 if the president or chairman of the company are among the top ten shareholders of the company, and 0 otherwise. Measured only for ChuoAoyama clients.	JCH, 2004
Industry Expert Auditor	Indicator that takes the value 1 when the audit firm audits greater than 20 percent of clients (weighted by total assets) in a given industry, and 0 otherwise.	Datastream
Abs Disc Accrual	Absolute value of total discretionary accruals estimated as per DeFond and Subramanyam (1998).	Datastream
M&A	Indicator variable that takes the value 1 when the firm has completed an M&A transaction in the prior two years, and 0 otherwise.	Thomson SDC
Suspension Announcement Returns	Stock returns on three-day window around the date the ChuoAoyama suspension was announced (May 10, 2006).	Datastream

The table provides definitions and data sources for all the variables in subsequent tests.
JCH = Japan Company Handbook.
USD = United States Dollar.

Does Mandatory IFRS Adoption Improve Information Comparability?

Rita W. Y. Yip

Danqing Young
The Chinese University of Hong Kong

ABSTRACT: This study examines whether the mandatory adoption of International Financial Reporting Standards (IFRS) in the European Union significantly improves information comparability in 17 European countries. We employ three proxies—the similarity of accounting functions that translate economic events into accounting data, the degree of information transfer, and the similarity of the information content of earnings and of the book value of equity—to measure information comparability. Our results suggest that mandatory IFRS adoption improves cross-country information comparability by making similar things look more alike without making different things look less different. Our results also suggest that both accounting convergence and higher quality information under IFRS are the likely drivers of the comparability improvement. In addition, we find some evidence that cross-country comparability improvement is affected by firms' institutional environment.

Keywords: *IFRS adoption; information comparability; institutional environment.*

Data Availability: *Data are available from commercial providers (Worldscope, DataStream, and I/B/E/S).*

I. INTRODUCTION

Demand for internationally comparable accounting information has increased significantly in recent years due to rapid growth in cross-country investment. One reflection of this trend is the widespread adoption of International Financial Reporting Standards (IFRS), including the mandatory adoption of IFRS in the European Union (EU) in 2005. Because mandatory IFRS are some of the most important financial reporting regulations in recent years, many studies have examined the various effects of their adoption (e.g., Capkun et al. 2008; Daske et

al. 2008; Armstrong et al. 2010; Horton and Serafeim 2010; Clarkson et al. 2011). However, to the best of our knowledge, the effect of IFRS adoption on cross-country information comparability has not been thoroughly examined, although better comparability has been commonly cited as one of the main benefits of IFRS adoption. The purpose of this study is, thus, to provide more empirical evidence on this issue.

Information comparability is "the quality of information that enables users to identify similarities in and differences between two sets of economic phenomena" (Financial Accounting Standards Board [FASB] 1980, 9; International Accounting Standards Board [IASB] 2010, A36). The Financial Accounting Standards Board further states that "greater comparability of accounting information, which most people agree is a worthwhile aim, is not to be attained by making unlike things look alike any more than by making like things look different" (FASB 1980, 42). These statements assert that there are two equally important facets of information comparability: the similarity facet, which indicates whether firms engaged in similar economic activities report similar accounting amounts, and the difference facet, which indicates whether firms engaged in different economic activities report dissimilar accounting amounts. Because improvement in one facet of comparability does not automatically lead to improvement in the other facet, the overall benefit of IFRS adoption on cross-country information comparability is contingent on whether adoption improves both facets of comparability, or at least improves one without impairing the other.

It is intuitively appealing that mandatory IFRS adoption improves the similarity facet of cross-country information comparability, and some empirical evidence from prior studies is consistent with this intuition (e.g., Ashbaugh and Pincus 2001; Chi 2009; Barth et al. 2011; DeFond et al. 2011). However, our view is that more research is required before a firm conclusion can be drawn, as prior studies either use input-based comparability measures, such as accounting rule variability and the number of accounting rules used on an announcement date (e.g., Chi 2009; DeFond et al. 2011), or rely on samples of voluntary adopters that likely have different reporting incentives from those of mandatory adopters (e.g., Ashbaugh and Pincus 2001; Barth et al. 2011). More importantly, the effect of IFRS adoption on the difference facet of cross-country comparability has not been addressed at all. This facet of comparability is important for mandatory IFRS adoption because "an overemphasis on uniformity may reduce comparability by making unlike things look alike" (IASB 2010, A36). For example, if IFRS allow fewer accounting choices than local accounting standards, then their adoption could force firms to treat different economic transactions in a more similar way, thus, diminishing the difference facet of comparability.[1] In this study, we test the effect of IFRS adoption on both facets of cross-country information comparability.

Following previous comparability studies (e.g., Bradshaw et al. 2009; Barth et al. 2011; DeFond et al. 2011; De Franco et al. 2011), we refer to firms in the same industry as similar firms and those in different industries as different firms.[2] We compare the cross-country information comparability of the similarity facet among similar firms from different countries, and we compare the cross-country information comparability of the difference facet among different firms from different countries, across the pre- and post-IFRS periods. Because increased cross-country comparability after IFRS, if any, could be affected by accounting convergence and/or higher quality financial information under IFRS than under local accounting standards, we also examine the two facets of within-country comparability to identify the possible drivers underlying the comparability improvement. As IFRS adoption generally reduces firms' accounting choices (e.g., Ashbaugh and Pincus 2001; Hoogendoorn 2006), an increase in both cross- and within-country comparability would suggest that both accounting convergence and higher quality information are the underlying drivers, whereas only an increase in cross-country comparability would suggest that convergence is the likely driver.

---

[1] As an example, some local accounting standards allow firms to use the acquisition method for acquisitions and the pooling method for mergers. However, IFRS allow only the acquisition method for all business combinations that are not under common control. As such, firms are forced to account for acquisitions and mergers in the same way.

[2] The underlying logic is that firms in the same industry have similar operational properties and face similar economic shocks, whereas firms in different industries may have different operational properties and face different industry-specific shocks. This definition is also supported by the common practice of analysts using firms in the same industry as benchmarks when analyzing a firm's financial statements.

We employ three proxies for information comparability. The first is the similarity of accounting functions measure developed by De Franco et al. (2011).[3] With this approach, accounting is essentially the mapping of economic transactions to financial statements, and information comparability can be defined as the similarity of firms' accounting functions that translate economic transactions into accounting data. The second proxy is the degree of information transfer, as measured by the association between the earnings surprise of an announcing firm and the contemporaneous stock price movements of other firms. The intuition underlying this measure is that an earnings announcement by a firm conveys information that has not previously been publicly available, and investors can abstract such information and adjust stock prices for other firms with comparable accounting. The third proxy is the similarity of the information content of earnings (ICE) and the information content of the book value of equity (ICBV), as measured by the long-window association between stock price and earnings and the book value of equity. Because ICE and ICBV capture the extent to which accounting earnings and the book value of equity reflect a firm's economic performance, firms that engage in similar economic activities should have a similar ICE and ICBV if their accounting systems are comparable.[4]

To test our research questions, we use data from 17 European countries in which listed firms must use IFRS to prepare their consolidated financial statements since 2005. We find that the comparability of accounting information for similar firms from different countries is significantly greater in the post-IFRS period (2005–2007) than in the pre-IFRS period (2002–2004), using all of the three comparability measures. However, using the measure of the similarity of accounting functions and information transfer,[5] we find that there are no discernible comparability changes among different firms from different countries across the two periods. Further, the comparability change in the similarity facet is greater than that in the difference facet. These results, thus, suggest that IFRS adoption improves the similarity facet of cross-country information comparability without discernibly impairing the difference facet of comparability. For within-country analysis, we find that the similarity facet of comparability increases for the accounting function measure, but not for the information transfer measure. However, the increase in the similarity facet of within-country comparability does not statistically differ from that of cross-country comparability using both measures. We, thus, interpret our results as consistent with the view that both accounting convergence and information quality play an important role in the observed IFRS effects.

As a supplemental test, we examine whether the improvement in the similarity facet of cross-country comparability is affected by firms' institutional environment. We classify a firm's institutional environment by the common law versus code law origin of the legal system in its home country, because a country's legal origin can proxy for a variety of institutional features, such as financial reporting incentives and the effectiveness of legal enforcement. We find that among similar firms from countries with the same legal origin, nearly all of the comparability measures increase after IFRS adoption. However, among similar firms from countries with different legal origins, only one comparability measure increases. Overall, these results provide some evidence that the institutional environment in the home countries of firms influences the effect of IFRS adoption on information comparability.

---

[3] De Franco et al. (2011) also develop another comparability measure that captures the similarity of two firms' economic events and accounting functions at the same time. Because we examine whether IFRS adoption improves the similarity of accounting functions, we do not use that measure here.

[4] We summarize comparability measures for each test in Figure 1.

[5] As explained in "Similarity of ICE and ICBV" in Section III, the similarity of ICE and ICBV measure is not applicable for the sample of different firms from different countries and the sample of similar firms from the same country.

This study contributes to the literature by providing empirical evidence on the association between mandatory IFRS adoption and information comparability. We address the impact of IFRS adoption on both the similarity and difference facets of comparability, whereas previous comparability studies address only the former. Our results suggest that mandatory IFRS adoption has an overall benefit in enhancing investors' ability to compare firms with similar fundamentals without discernibly reducing their ability to distinguish firms with different fundamentals. This study also extends the literature on the importance of institutions by documenting that IFRS adoption is more likely to improve comparability among firms with similar institutional environments. All of the findings may have practical implications for regulators and investors in countries considering IFRS adoption.

Section II discusses the literature and the differences between our study and previous studies. Section III describes the information comparability measures employed, and Section IV presents the empirical tests and their results. Section V presents supplemental and sensitivity tests, and Section VI concludes.

II. MOTIVATION AND LITERATURE REVIEW

Globalization in the last two decades has significantly increased the economic interaction among countries, which, in turn, has created demand for more internationally comparable accounting information. There are several potential benefits associated with enhanced information comparability. For example, both the FASB and the International Accounting Standards Board argue that more comparable information enables global markets to operate with less friction.[6] Several studies also suggest that greater information comparability facilitates international transactions and minimizes exchange costs (e.g., Turner 1983; Weber 1992; Choi et al. 1999).

The importance of comparable financial information in the global economy has led to growing research interest in information comparability. De Franco et al. (2011) develop two measures of accounting comparability and test their construct validity. They also use U.S. data to examine the benefits of comparability, finding that comparability is positively associated with analyst following and forecast accuracy, and negatively associated with forecast optimism and dispersion. Bradshaw et al. (2009) examine the association between accounting method variability (as a proxy for information comparability) and analyst characteristics using U.S. data, finding that a lower level of information comparability is associated with greater analyst forecast error and dispersion.

Several recent studies examine issues related to accounting comparability resulting from IFRS adoption. Using data from 26 countries from 1995 to 2006, Barth et al. (2011) find that the value relevance of earnings and equity book value is more comparable among non-U.S. firms after the application of the International Accounting Standards than when local accounting standards were used. Beuselinck et al. (2007) investigate the determinants of earnings comparability as proxied by the association between accruals and cash flows for the period 1990–2005 using data from 14 EU countries, finding that the association is not affected by mandatory IFRS adoption. DeFond et al. (2011) examine the benefits of increased accounting uniformity as a proxy for comparability, using data from 14 European countries. They find that foreign mutual fund ownership increases among mandatory adopters in countries with strong implementation credibility. Li (2010) cites enhanced comparability as the likely mechanism behind the cost of equity reduction in the EU after IFRS adoption. Wu and Zhang (2010) find an increased use of relative performance evaluation based on foreign peer firms' accounting information among European firms in the post-IFRS period.

---

[6] These arguments appeared in news releases by the FASB on February 27, 2006, and by the IASB on February 22, 2006.

Our study differs from these recent studies in two important ways. First, we address both the similarity and difference facets of comparability, whereas the previous studies only address issues related to the former. Second, we examine a different research question and, thus, use different comparability measures, sample periods, and sample firms. For example, whereas we examine the relation between comparability and mandatory IFRS adoption in 17 European countries, Barth et al. (2011) examine the comparability of mandatory and voluntary non-U.S. IFRS adopters and U.S. firms. Beuselinck et al. (2007) rely on a non-price-related comparability measure and data from the year of switch only (2005), whereas we use three price-related measures and three post-IFRS years of data.[7] Li (2010) and DeFond et al. (2011) use input-based and non-firm-specific comparability measures, whereas we employ output-based and firm-specific measures.[8]

III. SAMPLES AND COMPARABILITY MEASURES

Initial Sample

We collect data on listed firms in Austria, Belgium, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Luxembourg, The Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, and the United Kingdom from the Worldscope database. The number of firms included in the Worldscope database for each country is presented in Table 1, Panel A. We exclude financial, insurance, and real estate firms (SIC codes 6000–6999) from the sample because they have special operating properties and are subject to additional regulations. We also exclude firms that adopted IFRS before 2005 and firms that do not report consolidated financial statements from the sample. Finally, we restrict the sample to firms with a fiscal year ending in December to ensure that each firm has the same sample period. Table 1, Panel B, summarizes the sample selection procedure and the final sample size.

Comparability Measures and Related Samples

Similarity of Accounting Functions

This comparability measure was developed by De Franco et al. (2011), who argue that accounting is essentially the mapping of economic transactions to financial statements, and that accounting comparability can, thus, be defined as the similarity of accounting functions to translate economic transactions into accounting data. We first estimate each firm's accounting function by applying the following equation:

---

[7] Price-related comparability measures capture comparability from the perspectives of both investors and analysts. Because investors and analysts together are likely to be the largest groups using reported accounting information to make investment decisions, it is important to examine comparability from their perspectives.

[8] Following De Franco et al. (2011), we classify comparability measures that are computed using reported accounting data into the output-based category, and those that are based on accounting methods or accounting policies into the input-based category. For the dichotomy of firm-specific and non-firm-specific, measures that are computed using firm-level data are classified into the category of firm-specific, and those computed using industry- or country-level data are classified into the category of non-firm-specific.

TABLE 1
Sample Composition by Country and Initial Sample Procedures

Panel A: Sample Composition by Country from the Worldscope Database

Country	Number of Firms
Austria	98
Belgium	153
Denmark	191
Finland	127
France	818
Germany	966
Greece	293
Ireland	64
Italy	281
Luxembourg	42
The Netherlands	171
Norway	206
Portugal	60
Spain	143
Sweden	419
Switzerland	273
United Kingdom	1,951
Total	6,256

Panel B: Initial Sample Selection Procedures

Number of firms obtained from Worldscope	6,256
Exclusions:	
Financial institutions, insurance companies, and real-estate firms	(1,538)
Fiscal year not ending in December	(1,359)
Firms that voluntarily adopted IFRS before the mandatory requirement	(573)
Firms without consolidated accounts	(224)
Total number of firms in the initial sample	2,562

This table presents the sample composition by country and the initial sample selection procedure. Panel A presents the sample composition by country for the 6,256 firms collected from the Worldscope database. Panel B presents the initial sample selection procedure, which gives 2,562 firms.

$$ROA_{it} = \alpha^i + \beta^i RET_{it} + \varepsilon_{it}, \tag{1}$$

where ROA_{it} is the return on assets (an accounting performance measure) of firm i in period t, and is calculated as net income divided by total assets, and RET_{it}, a proxy for economic events, is the stock return of firm i in period t. The coefficients (α^i and β^i) represent the estimated accounting function of a firm. Using semiannual data, we estimate each firm's accounting function in the pre- and post-IFRS periods separately.

The similarity of accounting functions of firm i and firm j is then computed as follows. First, we translate firm i's economic activity into accounting ROA using its own accounting function (α^i and β^i) and the corresponding firm j's accounting function (α^j and β^j) for each semiannual year. Thus, we obtain the two expected ROAs, $E(ROA)^i_{it}$ and $E(ROA)^j_{it}$, and the absolute value of their difference for each semiannual year.[9] This process yields six absolute value *ROA* differences for the pre-IFRS period (2002–2004) and six differences for the post-IFRS (2005–2007) period. Second, we translate firm *j*'s economic activity into accounting *ROA* using its own accounting function (α^j and β^j) and firm *i*'s accounting function (α^i and β^i), and obtain the two expected *ROA*s, $E(ROA)^j_{jt}$ and $E(ROA)^i_{jt}$, and the absolute value of their difference for each semiannual year. Similarly, there are six differences for the pre-IFRS period and six differences for the post-IFRS period.[10] Third, we calculate the mean of the 12 differences in the pre-IFRS period (post-IFRS period) as the proxy for the information comparability of firms *i* and *j* in the pre-IFRS period (post-IFRS period). We multiply the mean by -1 so that a higher value represents greater comparability.

To generate a sample for a test of the similarity facet of cross-country comparability, we form pairs of firms from the same industry, based on the three-digit SIC code, but different countries. We rank the firms in each industry based on their total assets in 2006. For the largest firm, we choose a foreign firm with the closest total assets as its pair. We also require the ratio of the smaller value of total assets to the larger value in a pair to be greater than 50 percent. This procedure generates 133 pairs of firms. To form a sample to test the difference facet of cross-country comparability, we form pairs from different industries and countries. We require one firm in the pair to be a manufacturing firm (one-digit SIC code of 2 or 3) and the other to be a service firm (one-digit SIC code of 7 or 8).[11] For each manufacturing firm, we choose a service firm in a different country that is closest in terms of total assets. The ratio of the smaller value of total assets to the larger value must be greater than 50 percent. This procedure results in 148 pairs of firms. We employ the same procedure to form pairs from the same country, and generate 61 pairs of similar firms and 125 pairs of different firms.

Degree of Information Transfer

Previous studies have found associations between the information released by announcing firms and the returns of other firms in the same industry and country. For example, such information transfer has been documented with respect to the news in the earnings announcements (Firth 1976; Foster 1981; Clinch and Sinclair 1987; Han and Wild 1990; Hramnath 2002), stock split announcements (Tawatnuntachai and D'Mello 2002), management earnings forecasts (Baginski 1987; Han et al. 1989), and corporate security offerings (Szewczyk 1992). Such transfers occur because an announcement by a firm conveys information that has not previously been publicly available, and the stock market responds by reevaluating the value of non-announcing firms and adjusting their share prices accordingly. An important condition for information transfer through earnings announcements is comparable accounting earnings. If earnings are not comparable, then an earnings announcement by a firm is of little value in predicting the value of other firms, resulting in a low degree of information transfer. As such, the degree of information transfer reflects the level of information comparability.

We measure an earnings surprise for an announcing firm as the difference between reported earnings and *ex ante* expected earnings. The *ex ante* expected earnings are proxied by the mean analyst earnings forecast in the month immediately before the earnings release, which is obtained from the I/B/E/S database.[12] We calculate the abnormal stock returns of a non-announcing firm in the three days around the earnings release of the announcing firm (Day −1 to Day +1) using the following model:

---

[9] $E(ROA)^i_{it} = \alpha^i + \beta^i RET_{it}$ and $E(ROA)^j_{it} = \alpha^j + \beta^j RET_{it}$.

[10] $E(ROA)^i_{jt} = \alpha^i + \beta^i RET_{jt}$ and $E(ROA)^j_{jt} = \alpha^j + \beta^j RET_{jt}$.

[11] Because we assume that similar (different) firms face similar (different) economic shocks and have similar (different) operational properties, we use the three-digit SIC code to define similar firms to ensure that these firms are fundamentally similar, and use the one-digit SIC code to define different firms to ensure that they are fundamentally different.

[12] Only annual earnings surprises are used in this test because the data on announcement date for semiannual or quarterly earnings are not available for most sample firms.

$$U_{it} = RET_{it} - (\alpha^i + \beta^i RET_{mt}), \tag{2}$$

where U_{it} is the abnormal stock return of firm i on day t, and RET_{it} and RET_{mt} are the stock return of firm i and the market return of firm i's domestic market on day t, respectively.[13] We estimate the coefficients α^i and β^i separately for each fiscal year using data from Day −185 to Day −6, where Day 0 is the earnings announcement date of the announcing firm. The cumulative abnormal return of a non-announcing firm is the sum of its abnormal returns on the three days surrounding the earnings release date of the announcing firm. To reduce the cross-sectional correlation of prediction errors across clusters of non-announcing firms, we follow Baginski (1987) and use the mean cumulative abnormal return of all of the non-announcing firms in the empirical analyses.

To form a sample to test the similarity facet of cross-country comparability, we first identify all of the industries at the three-digit SIC code level that contain at least two firms from different countries. We rank the firms in each industry by their earnings announcement dates. To qualify as an announcing firm, the firm's earnings announcement window (Day −1 to Day +1) must not overlap with that of any other firm, to avoid the situation of non-announcing firms reacting to more than one earnings announcement on the same day. Each announcing firm is paired with all similar foreign firms with later earnings announcement dates that are of a similar size to the announcing firm (a ratio of the smaller total asset value to the larger value of greater than 50 percent). This approach yields 744 pair-year observations. To form a sample to test the difference facet of cross-country comparability, we match each announcing firm in the manufacturing sector with all of the foreign service firms with later earnings announcements and similar total assets, and *vice versa*. This sample contains 910 pair-year observations. For the two within-country samples, we implement the same procedure to form pairs within the same country, resulting in 195 and 630 pair-year observations for the tests of the similarity facet and difference facet of within-country comparability, respectively.

Similarity of ICE and ICBV

We employ the Ohlson (1995) model, in which a firm's market value is regressed on net income and equity book value, to test if ICE and ICBV are similar for two sets of firms:

$$MV_{it} = \beta_0 + \beta_1 NI_{it} + \beta_2 BV_{it} + \beta_3 D^x + \beta_4 D^x{*}NI_{it} + \beta_5 D^x{*}BV_{it} + \varepsilon_{it}, \tag{3}$$

where MV_{it} is the total market value of equity at the end of the fiscal year, NI_{it} is the net income,[14] and BV_{it} is the book value of equity.[15] These three variables are scaled by the number of outstanding common shares. The variable D^x is an indicator where x equals 1 when it is a country indicator, and 2 when it is an industry sector indicator. A significant β_4 and β_5 indicate that firms from different sets have a different ICE and ICBV, respectively, and, thus, a low degree of information comparability.

---

[13] The market return indices for Austria, Belgium, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Luxembourg, The Netherlands, Norway, Portugal, Spain, Sweden, Switzerland, and the United Kingdom are ATX, BEL, OMXC, OMXH, CAC, DAX, Athex, Ireland SE, MIB, LUX, AEX, OBX, PSI, IBEX, MX Stockholm, Swiss Market, and FTSE, respectively.

[14] In the Worldscope database, net income is defined as earnings (revenues less operating costs, depreciation, interest, taxes, and other expenses) less preferred dividends for non-U.S. firms.

[15] We use annual data to estimate Equation (3) because data on the semiannual book value of equity are missing for most sample firms in the Worldscope database.

To examine the similarity facet of cross-country information comparability, we estimate Equation (3) within each industry, as determined by three-digit SIC code, for every possible combination of two countries in the pre- and post-IFRS periods separately. We assign an ICE (ICBV) comparability score of 1 if β_4 (β_5) is insignificant (defined as a two-tailed p-value of more than 5 percent), and 0 otherwise. We require at least three firms in an industry in a given country to ensure that there are at least 18 observations in each regression. This process yields 210 regressions and, hence, 210 comparability scores for ICE and ICBV in the pre- and post-IFRS periods, respectively.

For the difference facet of within-country comparability analysis, we estimate Equation (3) using a set of firms from the manufacturing sector (one-digit SIC code of 2 or 3) and the other set of firms from the service sector (one-digit SIC code of 7 or 8), for every possible combination within a country in the pre- and post-IFRS periods separately. This results in 64 comparability scores for ICE and ICBV in each period. To estimate Equation (3), the sample firms must differ on only one of the industry sector or country dimensions captured by indicator D^x. Thus, this approach is not applicable to test either the difference facet of cross-country comparability, because sample firms are from different industry sectors and countries, or to test the similarity facet of within-country comparability, because sample firms are from both the same industry and the same country. Our comparability measures for each test are summarized in Figure 1.

IV. RESULTS

Results Using the Similarity of Accounting Functions Measure

We perform multivariate Regression (4) for four samples: similar firms from different countries, different firms from different countries, similar firms from the same country, and different firms from the same country:

$$Comp_{it} = \beta_0 + \beta_1 IFRS_t + \beta_2 TA\_Ratio_i + \beta_3 Com\_Code_i + \beta_4 Listing_i + ID_i, \tag{4}$$

where $Comp_{it}$ is the comparability of pair i in period t, and $IFRS_t$ is an indicator that equals 1 if t is the post-IFRS period, and 0 otherwise. A significant β_1 indicates that information comparability changes between the pre- and post-IFRS periods. The variable TA_Ratio_i is the ratio of the smaller value of total assets to the larger value of the two firms in a pair in 2006. Com_Code_i is an indicator that equals 1 when the home countries of the two firms in the pair have different legal origins, and 0 otherwise, and $Listing_i$ is an indicator that equals 1 if the two firms in a pair are both listed on at least one of the same stock exchanges, and 0 otherwise. These variables control for differences in firm size, institutional environment, and stock listing between the two firms, all of which may affect firms' reporting incentives and, hence, the comparability of their accounting information. These variables are all winsorized at the top and bottom 1 percent. ID_i is an industry indicator of a pair. For within-country analysis, we exclude *Com_Code* and *Listing* because they take the same value for all of the observations. For difference facet of comparability analysis, ID_i is excluded because each of the pairs consists of one manufacturing firm and one service firm. Following the discussion and practices in prior studies (e.g., Gow et al. 2010; DeFond et al. 2011), we adjust the standard errors by country clusters in the within-country analyses.

Table 2, Panel A, presents descriptive statistics for the four samples. The mean and median of *Comp* between cross-country similar and different firms, within-country similar and different firms, cross- and within-country similar firms, and cross- and within-country different firms do not statistically differ except that the mean of cross-country similar firms is smaller than that of cross-

This table presents the results of the tests using the similarity of accounting functions measure. Panel A presents the descriptive statistics for the variables used in the multivariate test. All of the variables are winsorized at the top and bottom 1 percent. Panel B presents the regression coefficients (t-statistics in parentheses). The base model is as follows:

$$Comp_{it} = \beta_0 + \beta_1 IFRS_t + \beta_2 TA\_Ratio_i + \beta_3 Com\_Code_i + \beta_4 Listing_i + ID_i.$$

For within-country analyses, *Com_Code* and *Listing* are excluded from the model because all of the observations equal 1, and the standard errors are adjusted by country clusters. For difference facet of comparability analysis, ID_i is excluded because each of the pairs consists of one manufacturing firm and one service firm. For analyses using a pooled sample of cross-country similar and different firms, the model includes an indicator variable, *Similar_Firm*, and its interaction with *IFRS*. For analyses using a pooled sample of cross- and within-country similar firms, the model includes an indicator variable, *Cross_Country*, and its interaction with *IFRS*.

Variable Definitions:
$Comp_{it}$ = information comparability between two firms in pair i in period t;
$IFRS_t$ = an indicator that equals 1 if t is a post-IFRS period, and 0 if t is a pre-IFRS period;
TA_Ratio_i = ratio of the smaller value of total assets to the larger value of the firms in a pair in 2006;
Com_Code_i = an indicator that equals 1 when the home countries of the two firms in a pair have different legal system origins, and 0 otherwise;
$Listing_i$ = an indicator that equals 1 if the two firms in a pair are listed on at least one of the same stock exchanges, and 0 otherwise;
ID_i = an industry indicator of a pair;
$Similar\_Firm_i$ = an indicator that equals 1 if *Comp* is the comparability between two similar firms, and 0 if it is between two different firms; and
$Cross\_Country_i$ = an indicator that equals 1 if *Comp* is the comparability between two similar firms from different countries, and 0 if it is between two similar firms from the same country.

country different firms (results are not tabulated).[16] Panel B reports the regression results. For the two cross-country analyses, the coefficient of *IFRS* (β_1) is positive and significant for the sample of similar firms (coefficient of 0.474, $p < 0.01$), but is close to 0 (0.009) and statistically insignificant for the sample of different firms.[17] We also compare the coefficient of *IFRS* between the samples of similar and different firms. We combine these two samples, and include an indicator for the observations from the sample of similar firms (*Similar_Firm*) and its interaction with *IFRS* in

---

[16] Seven pairs of firms have extremely small comparability values, mainly in the pre-IFRS period. When these pairs are excluded from the sample of cross-country similar firms, the mean comparability of the sample becomes similar to those of the other samples. When we estimate Equation (4) using the reduced sample, the coefficient of *IFRS* remains positive and significant (coefficient of 0.119, $p < 0.000$), and significantly greater than that of the sample of cross-country different firms.

[17] We follow Milton (1986) to estimate a minimum sample size necessary to reach a t-value of 2.00 and 1.68 for the samples used in the tests of the similarity of accounting functions and information transfer measures where the result for the variable of interest is insignificant. We find that all of our sample sizes are greater than their corresponding minimum sample sizes based on a t-value of 2.00.

Equation (4). We find that the coefficient on the interaction is positive and significant (coefficient of 0.465, $p < 0.01$). These results, thus, suggest that there is a significant improvement in the similarity facet, but not in the difference facet of cross-country comparability in the post-IFRS period.

For the two within-country analyses, the coefficient on *IFRS* is 0.655 and marginally significant for similar firms, and 0.720 but insignificant for different firms. We combine the samples of cross- and within-country similar firms, and include an indicator for the observations from the cross-country sample (*Cross_Country*) and its interaction with *IFRS* in the model. We find that the coefficient on the interaction is insignificant, suggesting that the effect of IFRS adoption on the similarity facet of cross-country comparability is similar to that of within-country comparability.

Results Using the Information Transfer Measure

The regression model using the measure of information transfer is as follows:

$$\begin{aligned} |NAF\_CAR_{it}| = {} & \beta_0 + \beta_1|AF\_UE_{it}| + \beta_2 IFRS_t + \beta_3|AF\_UE_{it}|*IFRS_t + \beta_4 AF\_Size_{it} \\ & + \beta_5 AF\_Analyst_{it} + \beta_6 AF\_Loss_{it} + ID_i, \end{aligned} \tag{5}$$

where $|NAF\_CAR_{it}|$ is the average absolute value of the cumulative abnormal returns of all the non-announcing firms within the three-day earnings release window of an announcing firm, and $|AF\_UE_{it}|$ is the absolute value of the unexpected earnings per share of the announcing firm, scaled by its stock price at the beginning of the fiscal year.[18] We use the absolute value of these two variables because information transfer can be positive or negative. A positive transfer takes place when a positive (negative) earnings surprise for an announcing firm indicates an unexpected improvement (deterioration) in market conditions, which positively (negatively) affects the stock prices of similar firms. A negative information transfer occurs when a positive (negative) earnings surprise for an announcing firm represents an increased (decreased) market share for that firm, which negatively (positively) affects the stock prices of similar firms (Kim et al. 2008). The indicator $IFRS_t$ equals 1 if t is a post-IFRS year, and 0 if it is a pre-IFRS year. We include the logarithm of total assets in U.S. dollars of the announcing firm (AF_Size_{it}) in the model because previous studies find that the earnings surprises of larger firms affect the stock prices of similar firms more than those of smaller firms (e.g., Atiase 1985; Firth 1996).[19] The variable $AF\_Analyst_{it}$ is the number of one-year-ahead earnings forecasts issued and revised for the announcing firm, controlling for the intensity of analyst activity. In addition, we include AF_Loss_{it} in the model to indicate whether the announcing firm is reporting a loss, as prior studies find that losses are less informative than profits (e.g., Hayn 1995). The industry indicator ID_i is also included in the cross- and within-country analysis for similar firms. Further, we adjust standard errors by country clusters based on the announcing firm's country in all of the four analyses.

Our variable of interest is the interaction between the absolute value of the unexpected earnings of the announcing firm and the indicator for the post-IFRS period ($|AF\_UE_{it}| * IFRS_t$). The coefficient on this interaction (β_3) indicates whether information comparability differs across the pre- and post-IFRS periods. The descriptive statistics for the variables for the four samples are summarized in Table 3, Panel A. We winsorize all of the variables at the top and bottom 1 percent. As Panel A shows, the mean absolute values of the cumulative abnormal return of the non-announcing firms range from 0.023 to 0.028, and are all greater than zero.

Table 3, Panel B, reports the regression results. For cross-country analysis, the coefficient β_3 on the variable of interest ($|AF\_UE_{it}| * IFRS_t$) is positive and significant ($p < 0.05$) for the sample of

---

[18] *NAF* and *AF* in the variable names denote Non-Announcing Firms and Announcing Firms, respectively.

[19] The Worldscope database provides accounting data in both the local currency and U.S. dollars.

*, **, *** Indicate significance at the 0.10, 0.05, and 0.01 levels, respectively, two-sided.

This table presents the results for the tests using the information transfer measure. Panel A presents the descriptive statistics for the variables in the multivariate test. All of the variables are winsorized at the top and bottom 1 percent. Panel B presents the regression coefficients (t-statistics in parentheses). The standard errors are clustered at the announcing firm's country level. The base model is as follows:

$$|NAF\_CAR_{it}| = \beta_0 + \beta_1|AF\_UE_{it}| + \beta_2 IFRS_t + \beta_3|AF\_UE_{it}|{*}IFRS_t + \beta_4 AF\_Size_{it} + \beta_5 AF\_Analyst_{it} + \beta_6 AF\_Loss_{it} + ID_i.$$

For analysis using a combined sample of similar and different cross-country firms, the model includes an indicator, *Similar_Firm*, and its two- and three-way interactions with *IFRS* and $|AF\_UE|$. For analysis using a pooled sample of cross- and within-country similar firms, the model includes an indicator, *Cross_Country*, and its two- and three-way interactions with *IFRS* and $|AF\_UE|$.

Variable Definitions:

$|NAF\_CAR_{it}|$ = average absolute value of the cumulative abnormal return of all of non-announcing firms within the three-day earnings release window of the announcing firm;

$|AF\_UE_{it}|$ = absolute value of the unexpected earnings per share of the announcing firm, scaled by its stock price at the beginning of the fiscal year;

$IFRS_t$ = an indicator that equals 1 if *t* is a post-IFRS year, and 0 if *t* is a pre-IFRS year;

AF_Size_{it} = size of the announcing firm, measured by the logarithm of total assets in U.S. dollars;

$AF\_Analyst_{it}$ = number of one-year-ahead earnings forecasts issued and revised for the announcing firm;

AF_Loss_{it} = an indicator of whether the announcing firm is reporting a loss;

ID_i = an industry indicator of a pair;

$Similar\_Firm_i$ = an indicator that equals 1 if the announcing and the non-announcing firms are similar firms, and 0 if they are different firms; and

$Cross\_Country_i$ = an indicator that equals 1 if the announcing and the non-announcing firms are from different countries, and 0 if they are from the same country.

similar firms with a coefficient of 0.001, but insignificant for the sample of different firms. Similar to the measure of accounting functions similarity, we pool the two samples and include an indicator for the observations from the sample of similar firms (*Similar_Firm*) and its interaction with $|AF\_UE_{it}| * IFRS_t$ in the model to test the equality of β_3 across the similar and different firms. We find that the coefficient on $IFRS_t * |AF\_UE_{it}| * Similar\_Firm_i$ has a value of 0.003 and is significant ($p < 0.05$), which suggests that IFRS adoption increases cross-country information transfer more for similar firms than for different firms.

For within-country analysis, the coefficient β_3 on $|AF\_UE_{it}| * IFRS_t$ is insignificant for both the sample of similar firms and the sample of different firms. However, the result from the test that examines the equality of β_3 between the cross-country and within-country similar firms shows that the coefficient on the variable of interest ($IFRS_t * |AF\_UE_{it}| * Cross\_Country_i$) is insignificant, suggesting that change in information transfer does not statistically differ between these two samples. Thus, the results using the information transfer measure are generally consistent with those using the similarity of accounting functions measure.

Results Using the Similarity of ICE and ICBV Measure

For the ICE and ICBV measures, we conduct tests for similar firms across countries and for different firms within the country. The descriptive statistics for the variables used in Equation (3) for these two samples are summarized in Table 4, Panel A. We winsorize all of the variables at the top and bottom 1 percent. Table 4, Panel B, presents the aggregate results from estimating Equation (3).

We perform a t-test to compare the mean comparability scores for ICE and ICBV across the pre- and post-IFRS periods. Table 4, Panel C, reports the results. For the sample of cross-country similar firms, the mean comparability scores for ICE and ICBV in the post-IFRS period are 0.890 and 0.862, respectively, indicating that among the 210 regressions of Equation (3), about 89.0 (86.2) percent show that the information content of earnings (book value of equity) does not statistically differ between the two sets of similar firms from two different countries. The 0.890 score for ICE is marginally greater than the corresponding pre-IFRS period score 0.829 ($p = 0.06$), and the 0.862 score for ICBV is significantly greater than the pre-IFRS period score of 0.748 ($p < 0.01$). This again suggests that IFRS adoption increases the similarity facet of cross-country information comparability. However, for the sample of different firms from the same country, the mean comparability scores for ICE and ICBV in the post-IFRS period (0.688 and 0.688) are not significantly different from the corresponding scores in the pre-IFRS period (0.594 and 0.625).

Summary of Results

Our comparability measures consistently indicate a significant improvement in the similarity facet, but an indiscernible change in the difference facet of cross-country information comparability after mandatory IFRS adoption. Further, the comparability improvement in the similarity facet is consistently greater than that in the difference facet. Together, these results suggest that IFRS adoption is, on the whole, beneficial, because it makes similar things look more alike without making different things look discernibly less different.

We also find some evidence of improvement in the similarity facet of within-country comparability. Importantly, our results show that there is no statistical difference between the similarity facet of comparability improvement in the cross-country sample and that in the within-country sample. Together, these results suggest that IFRS adoption improves information comparability among similar firms from different countries, as well as similar firms within the same country. As IFRS adoption generally reduces accounting choices for European firms (Hoogendoorn

TABLE 4 (continued)

---

*, **, *** Indicate significance at the 0.10, 0.05, and 0.01 levels, respectively.
This table presents the results of the tests using the ICE and ICBV measure. Panel A presents the descriptive statistics for the variables in the estimation of the following equation:

$$MV_{it} = \beta_0 + \beta_1 NI_{it} + \beta_2 BV_{it} + \beta_3 D^x + \beta_4 D^x{*}NI_{it} + \beta_5 D^x{*}BV_{it}.$$

All of the variables are winsorized at the top and bottom 1 percent. The sample of cross-country similar firms comprises 1,798 firms, and the sample of within-country different firms comprises 1,259 firms. Panel B presents the aggregate summary table for the estimates, which includes the means and two-tailed p-values showing whether the means are significantly different from 0. Panel C presents the results for the t-test of the difference in ICE and ICBV across the pre- and post-IFRS period for the sample of cross-country similar firms (n = 210) and the sample of within-country different firms (n = 64), respectively. An ICE (ICBV) comparability score of 1 is assigned if β_4 (β_5) is insignificant (defined as a p-value of more than 5 percent), and 0 otherwise.

Variable Definitions:
MV_{it} = total market value of equity at the end of the fiscal year, scaled by the number of outstanding common shares;
BV_{it} = book value of equity, scaled by the number of outstanding common shares;
NI_{it} = net income, defined as earnings (revenues less operating costs, depreciation, interest, taxes, and other expenses) less preferred dividends, scaled by the number of outstanding common shares; and
D^x = a country indicator when x equals 1, and an industry sector indicator when x equals 2.

2006), our results are consistent with the view that IFRS adoption improves information comparability via both accounting convergence and higher quality information.

V. SUPPLEMENTAL AND SENSITIVITY TESTS

Supplemental Tests for the Impact of Institutional Environment on Information Comparability

These supplemental tests examine whether the impact of IFRS adoption on the similarity facet of cross-country information comparability is influenced by a firm's institutional environment. On one hand, the importance of institutional factors to a firm's reporting incentives suggests that the comparability improvement resulting from IFRS adoption will be greater among firms from countries with similar institutional environments than among firms from countries with different institutional environments (e.g., Ball et al. 2003; Ball and Shivakumar 2005; Burgstahler et al. 2006). On the other hand, because countries with similar institutional environments usually had similar local accounting standards in the pre-IFRS period, the comparability improvement may be smaller among firms from these countries. We, thus, view this as an empirical question.

We classify a firm's institutional environment according to the origins of the legal system in its home country. For the tests using the accounting function measure, we form two samples. The first (second) sample includes all pairs of two similar firms from countries with the same (different) legal origin(s). We drop the variable Com_Code_i from Equation (4), and estimate the modified model for the two samples. Our results, presented in Table 5, Panel A, show that cross-country information comparability increases after IFRS adoption for both samples. We also test the equality of comparability improvement across the two samples by pooling the two samples and including an indicator for the observations from the first sample and its interaction with *IFRS*. We find that the comparability improvement does not statistically differ between the two samples.[20]

---

[20] Our results could be affected by the enforcement changes accompanied with IFRS adoption. For example, the EU passed the Transparency Directive in 2004 to establish disclosure requirements and facilitate IFRS compliance.

[a] Represents a test of mean difference across the pre- and post-IFRS periods.

[b] Represents a test of mean difference between the first and second samples.

This table presents the results for the additional tests of the impact of firms' institutions on their information comparability. Panel A presents the coefficients (t-statistics in parentheses) for the tests using the accounting function measure, in which the first (second) sample includes all of the pairs of two similar firms from countries with the same (different) legal origin(s). The variables are defined in Table 2. Panel B presents the coefficients (t-statistics in parentheses) for the tests using the information transfer measure. In the first (second) sample, the announcing firm's earnings surprise is paired with the average cumulative abnormal return of similar firms from countries with the same (different) legal origin(s) to the home country of the announcing firm. The variables are defined in Table 3. Panel C presents the results of tests using the ICE and ICBV measure, in which the first (second) sample includes all of the comparability scores estimated using two sets of firms from countries with the same (different) legal origin(s). The variables are defined in Table 4.

For the information transfer measure, we pair an announcing firm's earnings surprise with the average cumulative abnormal return of similar firms from countries with the same (different) legal origin(s) to the home country of the announcing firm in the first (second) sample. We find that the cross-country information transfer increases significantly in the post-IFRS period for the first sample, but not for the second sample. These results are reported in Table 5, Panel B.

For the ICE and ICBV measure, the first (second) sample includes all of the comparability scores estimated using the two sets of firms from countries with the same (different) legal origin(s). We compare the mean comparability scores across the pre- and post-IFRS periods in the two samples. We find that for ICE, there is no significant change in the mean comparability score across the two periods. For ICBV, however, the mean comparability score is significantly higher in the post-IFRS period than in the pre-IFRS period for the first sample with the same legal system origin, but not for the second sample. Table 5, Panel C, reports these results.

Overall, we find consistent evidence for enhanced cross-country information comparability among firms from countries with similar institutional environments. However, the results for firms from different institutional environments are mixed. Although the results using the measure of accounting function similarity suggest an improved comparability, the results using the other two measures suggest the opposite. This provides some evidence that the institutional environment in the home countries of firms is an important determinant of their information comparability.

Sensitivity Tests

We perform several sensitivity tests to assess the robustness of our results. First, because unusual accounting choices could be reflected in financial statements due to the anticipation of, and the transition to, IFRS during 2004 and 2005, we exclude these two years by defining the pre-IFRS period as 2002–2003 and the post–IFRS period as 2006–2007. The untabulated results based on the new sample periods are similar to those of the main tests.

Second, our results on the comparability improvement may be driven by increased similarity of firms' responses to economic shocks. To address this possibility, we examine whether there is a significant increase in firms' responses to economic shocks. Specifically, we compute the stock return correlation between two sets of similar firms from different countries for the pre- and post-IFRS periods separately. Because firms in the same industry face similar economic shocks, their stock returns should be correlated if they react to economic shocks in similar ways. A significantly higher mean correlation of stock return in the post-IFRS period than in the pre-IFRS period would suggest that there is an increase in the similarity of firms' responses to economic shock after mandatory IFRS adoption. We find that the mean correlation is significantly lower in the post-IFRS period (0.134) than in the pre-IFRS period (0.314), suggesting that firms' responses to economic shocks become less similar in the post-IFRS period. This, in turn, suggests that the similarity of firms' responses to economic shocks is unlikely to be the driver of improved information comparability in the post-IFRS period.

Third, because level regressions can be subject to econometric problems, we use a returns model to compare ICE across the pre- and post-IFRS periods. In our return model, annual stock returns are regressed on earnings scaled by price, a loss indicator, a country indicator, and the interaction between earnings and the country indicator. We run the regression for every possible combination of two countries in an industry in the pre- and post-IFRS periods separately, and assign a comparability score of 1 if the coefficient on the interaction term is insignificant, and 0 otherwise. We find that the mean comparability score in the post-IFRS period (0.990) is significantly higher than that in the pre-IFRS period (0.945), which is consistent with the finding from the level model that IFRS adoption improves the similarity facet of cross-country information comparability.

Fourth, because all of our comparability measures are based on equity price, we use a non-price-based comparability measure to examine the similarity facet of cross-country information comparability. Following Beuselinck et al. (2007), we assume that earnings comparability is affected by the timely recognition of losses by a firm's accounting system. We use the following modified model from Ball and Shivakumar (2005) to determine the comparability scores for every possible combination of two countries in an industry in the pre- and post-IFRS periods separately:

$$
\begin{aligned}
ACC_{jt} = {} & \beta_0 + \beta_1 CF_{jt} + \beta_2 NegCF_{jt} + \beta_3 CF_{jt}{*}NegCF_{jt} + \beta_4 D + \beta_5 D{*}CF_{jt} \\
& + \beta_6 D{*}NegCF_{jt} + \beta_7 D{*}CF_{jt}{*}NegCF_{jt} + \varepsilon_{jt}, \qquad (6)
\end{aligned}
$$

where ACC_t is accruals, defined as net income minus operating cash flow, and CF_t is operating cash flow. Both are scaled by the average total assets. $NegCF_t$ is an indicator of a negative CF, and D is a country indicator. The coefficient on the last item (β_7) indicates whether the accounting systems in the two countries recognize losses in accounting accruals in a similar fashion. We assign a comparability score of 1 if β_7 is insignificant, and 0 otherwise. We find that the mean comparability score in the post-IFRS period (0.861) is significantly higher than that in the pre-IFRS period (0.764). This result is consistent with the findings from those equity price-based comparability measures that cross-country information comparability improves for similar firms after mandatory IFRS adoption.

VI. CONCLUSION

One of the most commonly mentioned benefits of IFRS adoption is the improvement in cross-country information comparability. This study provides empirical evidence for this posited benefit using data from 17 European countries that adopted IFRS in 2005. We use three proxies for information comparability. The first is the similarity with which two firms translate economic events into their financial statements. The second is the degree of information transfer, and the third is the similarity of the information content of earnings and of the book value of equity.

Overall, our results are consistent with the view that mandatory IFRS adoption improves information comparability across countries. In particular, our results indicate a significant increase in the similarity facet of cross-country comparability in the post-IFRS period. However, we do not find such improvement in the difference facet of cross-country comparability, which implies that the mandatory IFRS adoption is not sufficient to achieve a full enhancement in comparability in the EU. Our results also suggest that both accounting convergence and higher quality accounting information are likely to be the mechanisms underlying the observed comparability improvement in the similarity facet. Further, our results suggest that comparability improvement is more likely to occur among firms from similar institutional environments than among firms from different institutional environments.

The Effect of *Ex Ante* Management Forecast Accuracy on the Post-Earnings-Announcement Drift

Li Zhang
Rutgers, The State University of New Jersey

ABSTRACT: I examine the effect of *ex ante* management forecast accuracy on the post-earnings-announcement drift when management forecasts about next quarter's earnings are bundled with current quarter's earnings announcements. I build a composite measure of *ex ante* management forecast accuracy that takes into account forecast ability, forecast difficulty, and forecast environment. The results show that the bundled forecasts with higher *ex ante* accuracy mitigate investors' under-reaction to current earnings and reduce the magnitude of the post-earnings-announcement drift.

Keywords: *post-earnings-announcement drift; bundled management forecast; ex ante forecast accuracy.*

Data Availability: *The data used in this paper are available from the sources listed in the text.*

I. INTRODUCTION

The post-earnings-announcement drift is one of the most intriguing market anomalies. Following earnings announcements, stock prices move in the same direction as that of earnings surprises for the subsequent 6 to 12 months, and the magnitude of the drift also increases with the magnitude of earnings news. Two main explanations have been advanced for this anomaly: a failure to adjust abnormal returns for risk, and a delayed response to earnings reports (Bernard and Thomas 1989). Existing evidence is more consistent with the market under-reaction explanation: investors underestimate the implications of current earnings for future earnings, and their under-reaction is corrected at future earnings announcement dates.[1]

This paper is based on my dissertation at London Business School. I thank Lakshmanan Shivakumar (my supervisor) for his continuous support and guidance, and Eli Amir, Divya Anantharaman, Maria Correia, Valentin Dimitrov, John Harry Evans III (editor), Francesca Franco, Sanjay Kallapur, Art Kraft, NingZhong Li, Xi Li, Yun Lou, Eli Talmor, Ane Tamayo, İrem Tuna, Oktay Urcan, Florin Vasvari, Paolo Volpin, and two anonymous referees for their helpful comments and suggestions.

Editor's note: Accepted by John Harry Evans III, with thanks to Sanjay Kallapur for serving as editor on a previous version.

[1] See Bernard and Thomas (1989, 1990), Ball and Bartov (1996), Livnat and Mendenhall (2006), and Shivakumar (2006), among others.

In this paper, I examine a prediction of the under-reaction explanation by investigating the effect of bundled management forecasts and their *ex ante* (perceived) accuracy on the post-earnings-announcement drift. Bundled management forecasts refer to forecasts of future earnings that are issued within one trading day of the current earnings announcement date, to yield a post-earnings-announcement drift window consistent with that in previous literature (Livnat and Mendenhall 2006).[2] Bundled management forecasts have become more prevalent recently, increasing from 10.7 percent of all management forecasts in 1996 to approximately 80 percent in 2007 (Rogers and Van Buskirk 2011). I focus on bundled management forecasts and their *ex ante* accuracy because they are pertinent to investigating whether management forecasts of future earnings, when issued together with current earnings announcements, help investors form expectations of future earnings promptly and mitigate the under-reaction to current earnings news. Other management forecasts, such as the forecasts issued two or more days after the current quarter earnings announcements, do not provide as timely information to accelerate investors' reaction to current earnings news.[3]

I hypothesize that investors' response to bundled management forecasts depends on the *ex ante* forecast accuracy, which is distinguished from actual forecast accuracy that is revealed at future earnings announcements. If investors perceive that the bundled management forecasts lack accuracy, then they place less weight on the forecasts, and continue to extrapolate future earnings based on their own information sets. Only when these bundled forecasts have high perceived accuracy do investors incorporate the bundled management forecasts into their expectations of future earnings, thereby possibly mitigating the post-earnings-announcement drift.

This paper is closely related to two recent studies by Li and Tse (2008) and Wang (2008), who examine a similar research question. However, Li and Tse (2008) and Wang (2008) do not demonstrate that investors' response to the bundled management forecasts depends on forecasts' perceived accuracy. In contrast, these two papers examine the effect of the subsequent actual forecast accuracy on the post-earnings-announcement drift, although investors do not know the actual forecast accuracy when the bundled management forecasts are issued.

Further, I investigate the interaction between *ex ante* accuracy and actual accuracy of the bundled forecasts in mitigating the post-earnings-announcement drift, which has not been addressed by prior literature or the contemporaneous papers. Specifically, if bundled forecasts have high *ex ante* accuracy but turn out to have low actual accuracy, then investors' expectations of future earnings are not improved by these forecasts; hence the post-earnings-announcement drift may not be mitigated.

In this paper, I construct a forecast accuracy prediction model that is based on the relation between actual forecast accuracy and forecast properties. The results suggest that a management forecast is likely to have higher actual accuracy if the prior forecast accuracy is higher, if the forecast horizon is shorter, if the forecast difficulty is lower, if the forecast news is less extreme, if the prior stock return is higher, or if the firm's market-to-book ratio is higher. For each management forecast, I measure the *ex ante* forecast accuracy using the estimated relationship and the current forecast properties.[4] Compared with other *ex ante* accuracy measures used in the prior literature (the prior forecast accuracy, or the previous four quarters' average forecast accuracy), this estimated *ex ante* forecast accuracy measure is more significantly associated with the actual forecast accuracy.

---

[2] This approach is similar in spirit to that employed by Rogers and Van Buskirk (2011), in which bundled management forecasts refer to the forecasts issued within two days of the earnings announcement date.

[3] If management forecasts of future earnings are issued before, not along with, current earnings announcements, then they may help investors understand the implications of current earnings for future earnings as well. I discuss these forecasts in the robustness tests.

[4] To avoid look-ahead bias, the estimated relationship is based on the data available within the four quarters before the management forecast is announced. The estimation is also conducted separately for annual forecasts and quarterly forecasts.

From the second quarter of 1997 to the second quarter of 2007, 10,641 quarterly earnings announcements are bundled with the management forecasts of next quarter's earnings, in a sample of 72,851 quarterly earnings announcements.[5] Of these bundled management forecasts, 6,267 are perceived to be more accurate (i.e., the estimated accuracy is higher than the median).[6] Firms that have bundled forecasts with higher *ex ante* accuracy tend to be significantly larger and have smaller analyst forecast dispersion, more analyst following, higher institutional shareholding, higher trading volume in the past, higher stock price, lower earnings persistence, less negative earnings surprises, and more responsive analysts than firms that have bundled forecasts with lower *ex ante* accuracy.

The main empirical results suggest that bundled management forecasts, on average, do not mitigate the post-earnings-announcement drift when other drift-related variables are controlled. Consistent with the prediction, the bundled management forecasts reduce the magnitude of the post-earnings-announcement drift when they have higher *ex ante* forecast accuracy. The results hold after a battery of robustness checks. I also use a Heckman two-stage approach to solve the self-selection bias of issuing bundled management forecasts, and the inferences remain unchanged. Further, I investigate whether the effect of *ex ante* forecast accuracy on the drift varies with the actual forecast accuracy. This additional analysis shows that the post-earnings-announcement drift is not mitigated if the bundled forecasts have higher *ex ante* accuracy but lower actual accuracy.

Despite prior research on the existence and causes of the post-earning-announcement drift, there is limited evidence about the effect of voluntary disclosure on the drift. By demonstrating the mitigating effect of bundled forecasts with higher *ex ante* accuracy on the drift, this paper adds to the evidence supporting the under-reaction explanation for the post-earnings-announcement drift. This paper also adds to the evidence about the interaction between mandatory reporting and voluntary disclosure, which has not been adequately investigated in the prior literature (Beyer et al. 2010).

Previous literature (Rogers and Stocken 2005) shows that the market filters out the predicted forecast error in the short event window, especially for good news management forecasts. This paper extends the literature by analyzing how the estimated forecast accuracy affects investors' ability to interpret the implications of current earnings for future earnings in the intertemporal setting. Consistent with the argument in Verrecchia (1980) that the rapidity of price reaction to the information varies with investors' consensus judgment of the information's accuracy, I show that investors respond promptly to bundled management forecasts that have higher *ex ante* accuracy.

This paper distinguishes between *ex ante* and actual management forecast accuracy in affecting the post-earnings-announcement drift. In contrast to Li and Tse (2008) and Wang (2008), I investigate the crucial role performed by *ex ante* forecast accuracy in providing incremental information to resolve the uncertainty related to future earnings. I also provide further evidence that the mitigating effect of the *ex ante* forecast accuracy varies with the actual forecast accuracy, which accentuates the interaction between these two forecast accuracy measures.

Finally, Graham et al. (2005) find that managers make voluntary disclosures primarily to develop a transparent reporting reputation and to increase the predictability of future earnings. In this paper's context, managers may be motivated to build a transparent information environment by issuing bundled management forecasts. However, for the announced forecasts to be promptly reflected in the stock price and to resolve the uncertainty related to future earnings, managers need to promote the perceived forecast accuracy.

---

[5] The main analysis focuses on the bundled management forecasts that are about next quarter's earnings. Compared with the bundled management forecasts of two-quarter-ahead (and beyond) earnings, these forecasts are most likely to mitigate investors' under-reaction to current earnings.

[6] The estimated accuracy of bundled management forecasts is benchmarked with the median accuracy of all management forecasts, including bundled management forecasts and unbundled management forecasts. Therefore, more than half (10,521 × 1/2) of the bundled management forecasts are perceived to be more accurate.

The rest of the paper proceeds as follows. Section II reviews the literature and develops the hypothesis. Section III discusses the sample, and constructs the *ex ante* forecast accuracy measure. Section IV presents the empirical results. Section V concludes.

II. LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Voluntary disclosure, especially forecasts of future performance, is not subject to the restrictions of accounting standards, and managers can use such disclosure to communicate their private information to investors. Since the enactment of Regulation Fair Disclosure, it has become increasingly common for firms to announce current earnings and management forecasts about future earnings simultaneously, partly because of the greater use of earnings-related conference calls along with or close to earnings announcements (Rogers and Van Buskirk 2011).

The under-reaction explanation for the post-earnings-announcement drift suggests that the speed with which investors incorporate the implications of current earnings into their expectations of future earnings is associated with the magnitude of the drift (Bernard and Thomas 1990; Ball and Bartov 1996; Soffer and Lys 1999; Livnat and Mendenhall 2006; Shivakumar 2006; Zhang 2008). If managers issue their forecasts of future earnings along with the current earnings announcements, then investors have more information with which to resolve the uncertainty related to the future periods' earnings. Hence, the post-earnings-announcement drift may be affected.

Even though investors can verify management forecasts by comparing them to subsequently announced actual earnings, not all management forecasts are accurate, i.e., close to actual earnings, because of managers' intentional bias or forecast difficulty (Lev and Penman 1990; Rogers and Stocken 2005). For example, Hutton and Stocken (2009) find that only about half of the management forecasts are more accurate than the median analyst forecasts. Previous literature documents that investors are likely to estimate the accuracy of the management forecasts and incorporate it into their reaction to the forecast news. Rogers and Stocken (2005) investigate the market's response to the predicted forecast errors and find that, for good news management forecasts, the market's response varies with the predicted forecast errors. Ng et al. (2010) find that forecast credibility mitigates investors' under-reaction to management forecast news. They use various forecast credibility measures, including prior forecast accuracy, firm-level litigation risk, industry concentration, and research and development intensity.

In this paper, I argue that investors incorporate the bundled forecasts into their expectations of future earnings when the forecasts have high *ex ante* accuracy. *Ex ante* accuracy is the investors' perception of the forecast accuracy *before* the related actual earnings are announced, and it is different from actual accuracy that is revealed *when* the related actual earnings are announced. Because investors do not know the actual accuracy when the bundled forecasts are issued, they should only rely on the *ex ante* accuracy to determine whether the bundled forecasts help resolve the uncertainty related to future earnings. If investors perceive the bundled forecasts to be accurate, then they incorporate these forecasts into their expectations of future earnings and accelerate their reaction to current earnings news.

If some bundled forecasts have high *ex ante* accuracy, but turn out to have low actual accuracy, then investors' expectations of future earnings are not improved. To the extent that bundled forecasts provide incremental information to accelerate investors' reaction to current earnings and reduce the magnitude of the post-earnings-announcement drift, I expect the drift to continue for such forecasts. The main objective of this paper is to examine the effect of *ex ante* forecast accuracy on the post-earnings-announcement drift.[7] Further, I investigate whether the mitigating effect of the *ex ante* accuracy varies with the actual accuracy.

A concurrent study by Li and Tse (2008) finds that bundled management forecasts in general mitigate the post-earnings-announcement drift, which is different from this paper's prediction and from the results shown in Section IV. Another contemporaneous paper by Wang (2008) also finds that earnings announcements with previously issued management forecasts have lower magnitude of the post-earnings-announcement drift.[8] Neither Li and Tse (2008) nor Wang (2008) demonstrates the crucial role *ex ante* management forecast accuracy performs, or explores the interaction between *ex ante* forecast accuracy and actual forecast accuracy in mitigating the post-earnings-announcement drift.

In a similar vein, Zhang (2008) finds that responsive analysts accelerate market reaction to earnings announcements, thereby mitigating the post-earnings-announcement drift.[9] She also finds that when earnings announcements are bundled with conference calls or management forecasts, analysts are more likely to be responsive. Compared with Zhang (2008), this paper focuses directly on the bundled management forecasts of next quarter's earnings, and incorporates their *ex ante* accuracy into the analysis.[10]

III. SAMPLE SELECTION, RESEARCH METHOD, AND DESCRIPTIVE STATISTICS

Sample Selection

I obtain management forecasts announced from 1995 to 2007 from First Call's Company Issued Guidance database. Because explicit forecast numbers are necessary for the calculation of the forecast accuracy, I include only point estimates and range estimates in the analysis of the association between actual forecast accuracy and forecast properties. Managers might pre-announce earnings after the corresponding fiscal period ends, and I exclude these pre-announcements from the management forecast sample.[11] Because management forecast error is deflated by the average stock price one week before the issuance of the management forecast, I delete the observations that do not have corresponding stock prices, or that have stock prices smaller than $1. I also exclude financial firms and firms whose shares are not traded on NYSE/AMEX/NASDAQ, or that have non-ordinary shares.

I obtain firms' actual earnings per share (EPS) data over the period 1997–2007 from the I/B/E/S database.[12] Next, I cross-check the earnings announcement dates in I/B/E/S with those in First Call, and delete the observations that have different earnings announcement dates.[13] Analyst

---

[7] This paper is a joint test of whether investors use all of the available forecast properties to estimate the forecast accuracy and whether they incorporate the forecasts with high estimated accuracy into their reaction to current earnings news.

[8] Footnote 24 discusses the potential reasons for the difference of the results.

[9] Zhang (2008) defines a responsive analyst as one who revises the forecast of next quarter's earnings within two trading days after the current quarter earnings announcement.

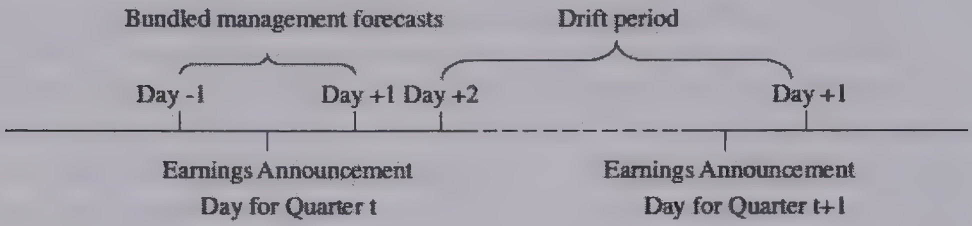
[10] Using a sample of 518 firms that initiated conference calls between 1994 and 2000, Kimbrough (2005) shows that the initiation of conference calls leads investors to respond in a more timely fashion to current earnings surprises. Initiation of conference calls is a one-off event in a firm's life, which says very little about how bundled management forecasts affect the post-earnings-announcement drift on a regular basis.

[11] The untabulated analysis shows that the actual accuracy of earnings preannouncements is significantly higher than that of ordinary management forecasts.

[12] This time range is selected because the *ex ante* forecast accuracy can be estimated during this period. Specifically, it is from the second quarter of 1997 to the second quarter of 2007.

[13] This paper uses the earnings numbers in I/B/E/S rather than Compustat because earnings in Compustat are restated and, hence, are not the actual earnings that investors observe and react to. See Livnat and Mendenhall (2006) for a comparison between I/B/E/S and Compustat.

FIGURE 1
Timeline for Measurement of Variables



Bundled management forecasts
Drift period
Day -1
Day +1
Day +2
Day +1
Earnings Announcement Day for Quarter t
Earnings Announcement Day for Quarter t+1

If the management forecast of Quarter $t+1$'s earnings is issued within one trading day around the earnings announcement date of Quarter t, then it is treated as the bundled management forecast. The post-earnings-announcement drift period starts two trading days after the earnings announcement date of Quarter t and ends on the first trading day after the earnings announcement date of Quarter $t+1$.

forecasts are non-split-adjusted forecasts from I/B/E/S. The most recent consensus analyst forecast used to calculate the unexpected earnings is the median of the analyst forecasts issued within 90 days before quarterly earnings announcements.[14]

Figure 1 shows the timeline for measurement of variables. The earnings announcement window is from trading day −1 to trading day +1 around the earnings announcement date (trading day 0) of Quarter t. Consistent with the prior literature (Livnat and Mendenhall 2006), the drift window starts two trading days after the earnings announcement date of Quarter t and ends on the first trading day after the earnings announcement date of Quarter $t+1$. The main analysis focuses on the management forecasts of the next quarter's earnings issued within the earnings announcement window, and investigates their *ex ante* accuracy on the drift period return.[15]

Measurement of *Ex Ante* Management Forecast Accuracy

I propose that investors base their estimate of *ex ante* management forecast accuracy on a variety of forecast properties. Rogers and Stocken (2005) develop a management forecast error prediction model that identifies the following explanatory variables: forecast horizon, forecast difficulty, forecast news, previous stock return, litigation risk, industry concentration, financial distress, market value to book value of equity ratio, and firm size. This prediction model in Rogers and Stocken (2005), specifically, is about forecast bias, while forecast accuracy is subject to not only the effects of intentional forecast bias, but also forecast difficulty and forecast ability. When firms' operating environments are more volatile, their earnings-generating processes are subject to multiple contingencies. Although managers may truthfully reveal the private information through management forecasts, these forecasts are still subject to random forecast errors, owing to high forecasting difficulty. The actual accuracy of firms' prior forecasts is a proxy for firm-level management forecasting ability, which influences investors' perceptions of current forecast accuracy (Hutton and Stocken 2009). I also incorporate the differential accuracy levels of bundled versus unbundled management forecasts (Rogers and Van Buskirk 2011).

The following model is used to estimate the association between the actual management forecast accuracy and the preceding forecast properties:

---

[14] The results are similar if I use the latest individual analyst forecast to calculate the unexpected earnings, following Zhang (2008).

[15] I also include the annual forecasts that have the next quarter ends as the forecast period end dates.

$$\begin{aligned} ActualAccuracy_{i,t} = {} & \alpha_0 + \alpha_1 PriorAccuracy_{i,t} + \alpha_2 ForecastHorizon_{i,t} + \alpha_3 ForecastDifficulty_{i,t} \\ & + \alpha_4 ForecastNews_{i,t} \times GoodNews_{i,t} + \alpha_5 ForecastNews_{i,t} \times BadNews_{i,t} \\ & + \alpha_6 CAR_{i,t} + \alpha_7 Litigation_{i,t} + \alpha_8 Concentration_{i,t-1} + \alpha_9 Distress_{i,t-1} \\ & + \alpha_{10} MB_{i,t-1} + \alpha_{11} Size_{i,t-1} + \alpha_{12} Bundle_{i,t} + \varepsilon_{i,t} \end{aligned} \tag{1}$$

where the variables are defined as follows:

Actual forecast accuracy (*ActualAccuracy*): Following Ng et al. (2010), management forecast accuracy is calculated as:

$$ActualAccuracy = -1 \times ABS\left(\frac{ActualEarnings - ManagementForecast}{Price}\right)$$

where *Price* refers to the average stock price one week before the management forecast announcement date. A management forecast is more accurate if *ActualAccuracy* is higher (closer to 0);

Prior forecast accuracy (*PriorAccuracy*) refers to the actual accuracy of the prior management forecast. In order for investors to know the actual accuracy of the prior forecasts, the actual earnings related to the forecasts should be announced before the current management forecast announcement date;

Forecast horizon (*ForecastHorizon*) is calculated as the management forecast period end date minus the announcement date, deflated by 360;

Forecast difficulty (*ForecastDifficulty*) is developed by performing Principal Axis Factoring over analyst forecast dispersion, the standard deviation of previous analyst forecast errors, firm's prior performance, future performance forecasted by the management, stock return volatility, bid-ask spread, and forecast width (see Rogers and Stocken 2005);

Forecast news (*ForecastNews*) is calculated as the management forecast minus the consensus analyst forecast, deflated by *Price*. *GoodNews* is an indicator variable that equals 1 if *ForecastNews* is non-negative, and 0 otherwise. *BadNews* is an indicator variable that equals 1 if *ForecastNews* is negative, and 0 otherwise; and

Other control variables: *CAR* is the firm's abnormal stock return cumulated from day −120 to day −1 relative to the management forecast announcement day. *Litigation* is an indicator variable that equals 1 if the firm is in industries with high litigation risk (Standard Industrial Classification codes 2833–2836, 3570–3577, 3600–3674, 5200–5961, 7370–7374, 8731–8734), and 0 otherwise. *Concentration* is measured by the Herfindahl index using the revenues of firms sharing the same four-digit SIC code. *Distress* is an indicator variable that equals 1 if the firm is in the most distressed decile predicted by Ohlson's (1980) bankruptcy model, and 0 otherwise. *MB* is the firm's market value of equity deflated by the book value of equity. *Size* is the natural log of the firm's total assets. *Concentration, Distress, MB*, and *Size* are calculated using the most recent accounting data prior to the announcement of the management forecast. *Bundle* is an indicator variable that equals 1 if a management forecast is issued within one trading day around the earnings announcement date, and 0 otherwise.

I estimate Model (1) separately for 21,790 quarterly forecasts and 20,701 annual forecasts issued from year 1995 to year 2007. The results are presented in Panel A of Table 1. Actual forecast accuracy is positively related to prior management forecast accuracy. Actual forecast accuracy is also higher when the forecast horizon is shorter. The significantly negative coefficient on *ForecastDifficulty* suggests that this latent variable effectively captures the difficulty that managers face in accurately forecasting future earnings. The coefficients on *ForecastNews* × *GoodNews* and *ForecastNews* × *BadNews* indicate that actual forecast accuracy is negatively associated with the

*, **, *** Indicate significance at the 10 percent, 5 percent, and 1 percent levels, respectively.

All continuous variables are winsorized at the 1 percent and 99 percent levels.

t-statistics are in parentheses, and are based on standard errors clustered on the firm level.

This table presents results from the regression of actual management forecast accuracy (*ActualAccuracy*) on forecast properties. The management forecasts and the related actual earnings are announced from year 1995 to year 2007. The actual forecast accuracy is calculated as: *ActualAccuracy* = −1 × *ABS(ActualEarnings* − *ManagementForecast)/Price*. *Price* is the average stock price one week before the management forecast announcement date. *PriorAccuracy* is the actual accuracy of the prior management forecast. The actual earnings related to the prior forecast should be announced before current management forecast announcement day. *ForecastHorizon* is the current management forecast horizon, calculated as the management forecast period end date minus the announcement date, deflated by 360. *ForecastDifficulty* is developed by performing Principal Axis Factoring over analyst forecast dispersion, standard deviation of previous analyst forecast errors, firm performance, predicted loss, stock return volatility, bid-ask spread, and forecast width, as in Rogers and Stocken (2005). *ForecastNews* is calculated as the management forecast minus the consensus analyst forecast, deflated by *Price*. *GoodNews* is an indicator variable that equals 1 if *ForecastNews* is non-negative, and 0 otherwise. *BadNews* is an indicator variable that equals 1 if *ForecastNews* is negative, and 0 otherwise. *CAR* is the firm's abnormal stock return cumulated from day −120 to day −1 relative to the management forecast announcement day. *Litigation* is an indicator variable that equals 1 if the firm is in industries with high litigation risk (Standard Industrial Classification codes 2833–2836, 3570–3577, 3600–3674, 5200–5961, 7370–7374, 8731–8734), and 0 otherwise. *Concentration* is measured by the Herfindahl index using the revenues of firms sharing the same four-digit SIC code. *Distress* is an indicator variable that equals 1 if the firm is in the most distressed decile predicted by the Ohlson bankruptcy model, and 0 otherwise. *MB* is the firm's market value of equity deflated by book value of equity. *Size* is the natural log of the firm's total assets. *Bundle* is an indicator variable that equals 1 if the management forecast is issued along with the earnings announcement, and 0 otherwise.

*** Indicates significance at the 1 percent level.

t-statistics are in parentheses, and are based on standard errors clustered on the firm level.

This table presents results from the regression of actual management forecast accuracy (*ActualAccuracy*) on *ex ante* forecast accuracy measures. *ActualAccuracy* and *PriorAccuracy* are defined in the notes to Panel A. *EstimatedAccuracy* is the *ex ante* accuracy measure developed by Model (1). The *EstimatedAccuracy* of 20,929 quarterly management forecasts and 20,148 annual management forecasts can be estimated using Model (1). These management forecasts are issued from the second quarter of year 1997 to the second quarter of year 2007. *AverageAccuracy* is the prior average actual forecast accuracy, and the actual earnings related to the prior management forecasts are announced during the previous four quarters relative to the current announcement quarter.

[a] I delete 10,513 management forecasts for which *AverageAccuracy* cannot be calculated, because managers did not issue forecasts for the earnings that are announced in the previous four quarters.

magnitude of the management forecast news. Previous stock return is positively related to actual forecast accuracy, suggesting that managers tend to forecast more accurately if they are under less share-price pressure. The actual accuracy of an annual forecast is likely to be higher when the forecast is bundled with an earnings announcement.

Using the above prediction model, I build an *ex ante* forecast accuracy measure by applying the estimated coefficients to the current forecast properties. For every consecutive four calendar quarters, I use the actual quarterly (annual) management forecast accuracy and other forecast properties to estimate the coefficients of Model (1). To avoid look-ahead bias, I use these estimated coefficients to obtain the *ex ante* accuracy of the quarterly (annual) management forecasts issued in the following calendar quarter. For example, I first obtain the quarterly earnings announcements made from the first quarter of 1999 to the fourth quarter of 1999 and the management forecasts of these earnings. Next, I estimate Model (1) using the actual accuracy of these management forecasts and other forecast properties. Finally, I use the estimated coefficients to compute the *ex ante* accuracy of the quarterly forecasts announced in the first quarter of 2000. In this way, the *ex ante* accuracy of 20,929 quarterly forecasts and 20,148 annual forecasts issued from the second quarter of 1997 to the second quarter of 2007 is estimated.[16]

---

[16] The estimation is conducted separately for quarterly management forecasts and annual management forecasts. The *ex ante* accuracy of forecasts announced before the second quarter of 1997 cannot be estimated because there are not enough observations to generate meaningful coefficients for the prediction model.

Previous literature has used other *ex ante* accuracy measures. Ng et al. (2010) use the actual accuracy of the prior management forecast, and Li and Tse (2008) use the previous four quarters' average management forecast accuracy. Panel B of Table 1 reports the association between the actual forecast accuracy (*ActualAccuracy*) and the multiple *ex ante* accuracy measures, including the estimated accuracy (*EstimatedAccuracy*) developed by Model (1), the prior forecast accuracy (*PriorAccuracy*), and the previous four quarters' average forecast accuracy (*AverageAccuracy*). *EstimatedAccuracy* has the highest association with the actual forecast accuracy.[17] The coefficient of the univariate regression is 0.752, and the adjusted R^2 is 24.14 percent.

In the following analyses, I transform the *EstimatedAccuracy* values into indicator variables based on the previous four quarters' cut-offs. The indicator variable *Dummy_EstimatedAccuracy* equals 1 if *EstimatedAccuracy* is greater than the median, and 0 otherwise. Similarly, *Dummy_PriorAccuracy* equals 1 if *PriorAccuracy* is greater than the median, and 0 otherwise. *Dummy_AverageAccuracy* equals 1 if *AverageAccuracy* is greater than the median, and 0 otherwise.

Test of the Effect of *Ex Ante* Forecast Accuracy on the Post-Earnings-Announcement Drift

I examine the effect of *ex ante* management forecast accuracy on the post-earnings-announcement drift by estimating the following model:

$$\begin{aligned} ADJ\_RET_{i,t} = {} & \beta_0 + \beta_1 DSUE_{i,t} + \beta_2 D\_BUNDLE_{i,t} + \beta_3 DSUE_{i,t} \times D\_BUNDLE_{i,t} \\ & + \beta_4 DSUE_{i,t} \times D\_BUNDLE_{i,t} \times Accuracy_{i,t} + \beta_5 DSUE_{i,t} \times DFD_{i,t} \\ & + \beta_6 DSUE_{i,t} \times DME_{i,t} + \beta_7 DSUE_{i,t} \times DAC_{i,t} + \beta_8 DSUE_{i,t} \times DVOL_{i,t} \\ & + \beta_9 DSUE_{i,t} \times DPRC_{i,t} + \beta_{10} DSUE_{i,t} \times DINS_{i,t} + \beta_{11} DSUE_{i,t} \times DEP_{i,t} \\ & + \beta_{12} DSUE_{i,t} \times EABADNEWS_{i,t} + \beta_{13} DSUE_{i,t} \times 4THQTR_{i,t} \\ & + \beta_{14} DSUE_{i,t} \times RESPONSIVE_{i,t} + \beta_{15} DFD_{i,t} + \beta_{16} DME_{i,t} + \beta_{17} DAC_{i,t} \\ & + \beta_{18} DVOL_{i,t} + \beta_{19} DPRC_{i,t} + \beta_{20} DINS_{i,t} + \beta_{21} DEP_{i,t} + \beta_{22} EABADNEWS_{i,t} \\ & + \beta_{23} 4THQTR_{i,t} + \beta_{24} RESPONSIVE_{i,t} + \varepsilon_{i,t} \end{aligned} \quad (2)$$

where *ADJ_RET* is the size-adjusted return over the drift window and equals the compounded raw return minus the compounded benchmark return of the same CRSP size decile and the same CRSP exchange index (NYSE/AMEX or NASDAQ) that the firm belongs to. Following Shumway and Warther (1999), when a firm is delisted because of poor performance (delisting code is 500, or from 520 to 584), the delisting return is assumed to be −35 percent if it is traded on NYSE/AMEX, and −55 percent if it is traded on NASDAQ.[18]

DSUE refers to the decile rank of earnings surprise, which is defined as the actual EPS minus the most recent consensus analyst forecast, scaled by the stock price at the end of the fiscal quarter. The earnings surprises are ranked into deciles within each calendar quarter using the cut-off values from the previous quarter, coded from 0 to 1 to yield *DSUE*. The coefficient of *DSUE* can be interpreted as the abnormal return earned on a zero-investment portfolio that takes a long position in the highest *DSUE* decile ($DSUE = 1$) and a short position in the lowest *DSUE* decile ($DSUE = 0$).[19]

When an earnings announcement is bundled with the management forecast of next quarter's earnings, the indicator variable *D_BUNDLE* equals 1, and 0 otherwise. I expect bundled management forecasts to mitigate the post-earnings-announcement drift when their *ex ante* forecast accuracy (*Accuracy*) is higher; hence $\beta_3 + \beta_4$ should be significantly negative. β_4 should be significantly negative as well, under the prediction that bundled forecasts with higher *ex ante* accuracy and bundled forecasts with lower *ex ante* accuracy should have different mitigating effects on the post-earnings-announcement drift.

---

[17] There is no strong reason to justify why the prior forecast accuracy should necessarily capture the *ex ante* forecast accuracy. Owing to managers' situational incentives (Mercer 2004) and the changing forecasting environment, I expect investors to use a more comprehensive, albeit more complicated, model to assess the accuracy of management forecasts, as reflected in Model (1).

[18] The percentage of firms delisted because of poor performance is 0.04 percent for the whole sample. The results are not affected if I simply delete these observations.

[19] See Doyle et al. (2006) and Zhang (2008).

Model (2) includes several control variables that prior studies have identified as being associated with the post-earnings-announcement drift. These are: analyst forecast dispersion (*DFD*); firm size (*DME*); analyst coverage (*DAC*); trading volume (*DVOL*); price (*DPRC*); institutional shareholding (*DINS*); earnings persistence (*DEP*); negative unexpected earnings (*EABADNEWS*); the fourth fiscal quarter earnings announcement (*4THQTR*); and analyst responsiveness (*RESPONSIVE*).[20]

The first three variables are proxies for information uncertainty. Analyst forecast dispersion is defined as the standard deviation of analyst forecasts divided by the stock price at the fiscal quarter end. Firm size is measured by the market value of equity at the fiscal quarter end. Analyst coverage is the number of analysts following the firm, based on the analyst estimates from I/B/E/S. Institutional shareholding is the percentage of institutional ownership, which is available from CDA/Spectrum. Following Mendenhall (2002), I estimate trading volume by multiplying the closing price and the shares traded from day −272 to day −21 relative to the earnings announcement day, and earnings persistence is the first-order serial correlation of seasonally differenced earnings estimated over the past 20 quarters. Stock price is the average stock price within one week before the earnings announcement. I transform these drift-related variables into decile ranks within each calendar quarter using the cut-off values from the previous quarter and code them from 0 to 1 (Mendenhall 2002). In this test, I use the inverse of the standard deviation of analyst forecasts to form *DFD*. Hence, consistent with *DME* and *DAC*, a higher value of *DFD* corresponds to lower analyst forecast dispersion and lower information uncertainty. *EABADNEWS* is an indicator variable that equals 1 if the unexpected earnings are negative, and 0 otherwise. *4THQTR* is an indicator variable that equals 1 if the earnings announcement is for the fourth fiscal quarter, and 0 otherwise. Following Zhang (2008), *RESPONSIVE* equals 1 if there is at least one analyst revising the forecast of next quarter's earnings within two trading days after the current quarter earnings announcement, and 0 otherwise.

Descriptive Statistics

Panels A and B of Table 2 present the means and medians of the drift-related variables conditional on the existence of the bundled management forecasts and the *ex ante* accuracy of the bundled forecasts. t-tests for means and Wilcoxon tests for medians are conducted over three subsamples: earnings announcements bundled with forecasts of higher *ex ante* accuracy (*D_BUNDLE* = 1 and *Dummy_EstimatedAccuracy* = 1); earnings announcements bundled with forecasts of lower *ex ante* accuracy (*D_BUNDLE* = 1 and *Dummy_EstimatedAccuracy* = 0); standalone earnings announcements (*D_BUNDLE* = 0).

From the second quarter of 1997 to the second quarter of 2007, among 72,851 quarterly earnings announcements, 10,641 quarterly earnings announcements are bundled with the management forecasts of next quarter's earnings.[21] Of the bundled management forecasts, 6,267

---

[20] See Rangan and Sloan (1998), Bartov et al. (2000), Mendenhall (2002), Zhang (2006), and Zhang (2008), among others.

[21] To achieve a cleaner test, I delete observations that have management forecasts of Quarter $t+1$ earnings issued before the earnings announcement date of Quarter t, or between the earnings announcement date of Quarter t and the earnings announcement date of Quarter $t+1$.

TABLE 2

TABLE 2 (continued)

Panel C: Comparison of Actual Forecast Accuracy and Estimated Forecast Accuracy across Subsamples

	No of Obs.	Actual Forecast Accuracy (*ActualAccuracy*)		Estimated Forecast Accuracy (*EstimatedAccuracy*)	
		Mean	Median	Mean	Median
Bundled quarterly management forecasts with higher *ex ante* accuracy	4,556	–0.0014	–0.0008	–0.0009	–0.001
Bundled quarterly management forecasts with lower *ex ante* accuracy	3,972	–0.0046	–0.0021	–0.0054	–0.004
Bundled annual management forecasts with higher *ex ante* accuracy	1,711	–0.0027	–0.0027	–0.0002	–0.0004
Bundled annual management forecasts with lower *ex ante* accuracy	447	–0.0091	–0.0028	–0.0158	–0.0132

The sample includes 72,851 quarterly earnings announcements from the second quarter of 1997 to the second quarter of 2007, among which 10,641 quarterly earnings announcements are bundled with the management forecasts of next quarter's earnings. Analyst forecast dispersion is the standard deviation of analyst forecasts divided by the stock price at the fiscal quarter end. Firm size is measured by the market value of equity at the fiscal quarter end. Analyst coverage is the number of analysts following the firm. Trading volume is estimated by multiplying the closing price and the shares traded from day –272 to day –21 relative to the earnings announcement day. Stock price is the average stock price within one week before the earnings announcement. Earnings persistence is the first-order serial correlation of seasonally differenced earnings estimated over the past 20 quarters. Institutional shareholding is the percentage of shares held by institutional investors at the quarter end that is closest to the earnings announcement day. *EABADNEWS* is an indicator variable that equals 1 if the unexpected earnings are negative, and 0 otherwise. *4THQTR* is an indicator variable that equals 1 if the earnings announcement is for the fourth fiscal quarter, and 0 otherwise. *RESPONSIVE* equals 1 if there is at least one analyst revising the forecast of next quarter's earnings within two trading days after current quarter earnings announcement, and 0 otherwise. *ActualAccuracy* is the *ex post* management forecast accuracy, which is calculated as: *ActualAccuracy* = –1 × *ABS(ActualEarnings – ManagementForecast)/Price*. *EstimatedAccuracy* is the *ex ante* accuracy measure developed by Model (1).

forecasts are perceived to be more accurate and 4,374 forecasts are perceived to be less accurate. Based on the t-tests for mean values, firms that have earnings announcements bundled with management forecasts of higher *ex ante* accuracy are significantly larger and have smaller analyst forecast dispersion, more analysts following, higher institutional shareholding, higher trading volume during the past, higher stock price, lower earnings persistence, less negative earnings surprises, and more responsive analysts than firms that have earnings announcements bundled with management forecasts of lower *ex ante* accuracy. Firms that have earnings announcements bundled with management forecasts of lower *ex ante* accuracy are not significantly different from firms that have standalone earnings announcements in terms of analyst forecast dispersion, but have a better information environment in terms of analyst coverage, institutional shareholding, and analyst responsiveness. The former firms are significantly smaller in market value of equity than the latter firms, based on the mean values, whereas the median values suggest the opposite. The different characteristics of these three categories of firms justify controlling the drift-related variables.

Panel C of Table 2 presents the actual forecast accuracy (*ActualAccuracy*) and the estimated forecast accuracy (*EstimatedAccuracy*) for the bundled quarterly (annual) forecasts with higher *ex ante* accuracy (i.e., *EstimatedAccuracy* is higher than the median) versus those with lower *ex ante* accuracy (i.e., *EstimatedAccuracy* is lower than the median). The statistics suggest that the estimated forecast accuracy measure correctly partitions management forecasts into the right subsamples, so that the actual forecast accuracy is in conformity with the *ex ante* forecast accuracy. For instance, the mean actual forecast accuracy of the bundled quarterly forecasts that have higher estimated accuracy is –0.0014, which exceeds the mean actual forecast accuracy (–0.0046) of the bundled quarterly forecasts that have lower estimated accuracy.

Table 3 reports the correlations among *DSUE*, *D_BUNDLE*, *Dummy_EstimatedAccuracy*, and other drift-related variables.[22] The Pearson product moment (Spearman rank order) correlations are presented above (below) the diagonal. Unless specified in parentheses with the corresponding two-sided p-values, all other correlations are significant at less than the 1 percent level. The indicator variable *D_BUNDLE* is significantly correlated with all drift-related variables. It is positively correlated with the inverse of analyst forecast dispersion (*DFD*), market value of equity (*DME*), analyst coverage (*DAC*), trading volume (*DVOL*), stock price (*DPRC*), institutional shareholding (*DINS*), earnings persistence (*DEP*), and analyst responsiveness (*RESPONSIVE*), and negatively correlated with the negative earnings surprise (*EABADNEWS*) and the fourth fiscal quarter earnings announcement (*4THQTR*). This univariate analysis indicates that firms in less uncertain information environments are more likely to issue bundled management forecasts than firms in more uncertain information environments.

IV. EMPIRICAL RESULTS

Main Analysis

Table 4 shows the regression results of Model (2).[23] Model (2a) tests the effect of the bundled management forecasts on the post-earnings-announcement drift. The average drift is 4.2 percent if earnings announcements are not bundled with the management forecasts of next quarter's earnings. The coefficient of the interaction term between *DSUE* and *D_BUNDLE* is –0.012, meaning that the

---

[22] The correlation of *Dummy_EstimatedAccuracy* and other variables should be interpreted with caution because *Dummy_EstimatedAccuracy* is set to be 0 for standalone earnings announcements for test purposes.

[23] Following Zhang (2008), I delete the observations with absolute value of studentized residuals greater than 2 in all regressions, to remove the effects of outliers. This estimation procedure decreases the sample size by about 4 percent and does not change the inferences.

Unless specified in parentheses with the corresponding two-sided p-values, all other correlations are significant at less than the 1 percent level.

This table presents the correlations among *DSUE*, *D_BUNDLE*, *Dummy_EstimatedAccuracy* and other drift-related variables. *DSUE* is the decile rank of the standardized unexpected earnings, and is coded from 0 to 1. *D_BUNDLE* equals 1 if an earnings announcement is bundled with the management forecast of next quarter's earnings, and 0 otherwise. *Dummy_EstimatedAccuracy* equals 1 if *EstimatedAccuracy* is greater than the median, and 0 otherwise. Analyst forecast dispersion (*DFD*), market value of equity (*DME*), analyst coverage (*DAC*), trading volume (*DVOL*), stock price (*DPRC*), institutional shareholding (*DINS*), and earnings persistence (*DEP*) are transformed into decile ranks within each calendar quarter, and coded from 0 to 1. *EABADNEWS*, *4THQTR*, and *RESPONSIVE* are defined in Table 2. The Pearson product moment (Spearman rank order) correlations are presented above (below) the diagonal.

bundled management forecasts decrease the drift by 1.2 percent; however, the effect is significant only at the 10 percent level (t-statistic $= -1.67$). β_3 becomes insignificantly negative (-0.004 with a t-statistic of -0.50) when other drift-related variables are controlled, as is shown in the estimation results of Model (2b). Therefore, the bundled management forecasts, in general, do not significantly decrease the magnitude of the post-earnings-announcement drift when other drift-related variables are controlled.[24]

Models (2c), (2d), (2e), and (2f) test the effect of the *ex ante* accuracy of bundled management forecasts on the post-earnings-announcement drift, using multiple measures of the *ex ante* accuracy. Models (2c) and (2d) use *Dummy_EstimatedAccuracy*, the *ex ante* accuracy measure developed in Model (1). When the drift-related variables are not controlled, the coefficient on the interaction term between *DSUE* and *D_BUNDLE* is -0.007 (t-statistic $= -0.90$), and the coefficient on *DSUE* × *D_BUNDLE* × *Dummy_EstimatedAccuracy* is -0.015 (t-statistic $= -2.53$). This result suggests that while the bundled management forecasts with lower estimated accuracy have no significant effect on the drift, the bundled forecasts with higher estimated accuracy significantly reduce the magnitude of the post-earnings-announcement drift by 2.2 percent ($\beta_3 + \beta_4$ with p-value of 0.004). In addition, the difference of the mitigating effects between these two kinds of forecasts is statistically significant as well. When the drift-related variables are controlled in Model (2d), the bundled forecasts with lower estimated accuracy do not mitigate the post-earnings-announcement drift at all ($\beta_3 = 0.005$ with t-statistic of 0.66). The bundled forecasts with higher estimated accuracy continue to have a significant mitigating effect on the drift, with a coefficient of -0.021 ($\beta_3 + \beta_4$ with p-value of 0.009).[25] Consistent with prior research, the magnitude of the post-earnings-announcement drift is significantly smaller when firms have higher trading volume, when the announced earnings are for the fourth fiscal quarter, and in the presence of responsive analysts after earnings announcements. Firm size and institutional ownership are shown to significantly reduce the drift in the previous literature (Foster et al. 1984; Bartov et al. 2000). However, these two variables do not have a significant mitigating effect on the drift when other drift-related variables are controlled.[26]

When the *ex ante* management forecast accuracy is measured by *Dummy_PriorAccuracy* or *Dummy_AverageAccuracy* in Models (2e) and (2f), β_4 and $\beta_3 + \beta_4$ become insignificant.[27] I interpret the results as the evidence that these *ex ante* forecast accuracy measures fail to correctly capture investors' perceived forecast accuracy.

I use the indicator variable *Dummy_EstimatedAccuracy* in the main analysis to better interpret the coefficients on the interaction terms, and highlight the different mitigating effects of the bundled forecasts with higher versus lower estimated accuracy. In the untabulated results, when I replace the

---

[24] This result is different from Li and Tse (2008) and Wang (2008) who examine a similar research question. Li and Tse (2008) find that bundled management forecasts mitigate the post-earnings-announcement drift on average. The sample period in Li and Tse (2008) is from 1996 to 2003, during which time only 4 percent of earnings announcements are bundled with management forecasts versus the 14.6 percent of earnings announcements that are bundled with management forecasts of next quarter's earnings in my sample period. I replicate their result and find it does not hold anymore if I expand their sample period to include 2004, 2005, 2006, and 2007, suggesting the difference in the results is primarily caused by the different sample periods. Wang (2008) finds that the post-earnings-announcement drift is less significant when management forecasts of future earnings are issued. However, Wang (2008) uses a test where the dependent variable is the future earnings announcement period return, which is different from the drift period return I use.

[25] I also use the unranked earnings news to test the robustness of the results. Untabulated analysis shows that β_3 is positive and β_4 is significantly negative when drift-related variables are controlled.

[26] A possible explanation for the size effect is that this variable is highly correlated with the trading volume, as is shown in the correlation matrix.

[27] I delete 1,871 observations for which *AverageAccuracy* cannot be calculated because managers did not issue forecasts for the earnings that are announced in the previous four quarters.

t-statistics (in parentheses) are based on standard errors clustered on the firm level. Year dummies are included in the regressions.

This table examines the effect of the *ex ante* management forecast accuracy on the post-earnings-announcement drift, controlling other drift-related variables. The sample includes 72,851 quarterly earnings announcements from the second quarter of 1997 to the second quarter of 2007. The dependent variable (*ADJ_RET*) is the drift-period return, which equals the compounded raw return minus the compounded benchmark return of the same CRSP size decile and the same CRSP exchange index (NYSE/AMEX or NASDAQ) that the firm belongs to. *DSUE* is the decile rank of the standardized unexpected earnings, and is coded from 0 to 1. The indicator variable *D_BUNDLE* equals 1 if an earnings announcement is bundled with the management forecast of next quarter's earnings, and 0 otherwise. *Dummy_EstimatedAccuracy* equals 1 if *EstimatedAccuracy* is greater than the median, and 0 otherwise. *Dummy_PriorAccuracy* equals 1 if *PriorAccuracy* is greater than the median, and 0 otherwise. *Dummy_AverageAccuracy* equals 1 if *AverageAccuracy* is greater than the median, and 0 otherwise. *DFD*, *DME*, *DAC*, *DVOL*, *DPRC*, *DINS*, *DEP*, *EABADNEWS*, *4THQTR*, and *RESPONSIVE* are defined in Tables 2 and 3.

indicator variables with the raw values, the coefficient on *DSUE* × *D_BUNDLE* × *EstimatedAccuracy* is −2.545 with a t-statistic of −3.77, consistent with the *ex ante* forecast accuracy being negatively associated with the magnitude of the drift. In contrast, the coefficient on *DSUE* × *D_BUNDLE* × *PriorAccuracy* or *DSUE* × *D_BUNDLE* × *AverageAccuracy* is not statistically significant.

In sum, the above results are consistent with the prediction that the bundled management forecasts of next quarter's earnings mitigate the post-earnings-announcement drift when the forecasts have high *ex ante* accuracy.

Endogeneity

The main analysis does not control for the self-selection of the decision to issue bundled management forecasts. Firms that choose to issue management forecasts of next quarter's earnings along with current-quarter earnings announcements may have certain characteristics that are associated with the relation between earnings and stock returns. To mitigate the issue of omitted correlated variables, I use the Heckman (1979) two-stage approach.

In the first stage, I adapt the probit model in Rogers and Van Buskirk (2011) to estimate the probability of issuing the bundled management forecast for each quarterly earnings announcement. Larcker and Rusticus (2010) point out that it is crucial to "develop the economic theory of the decision-making process" and identify the choice variables in the selection model. Lennox et al. (2012) provide corroborating evidence and support for this requirement. I propose that managers have the following motivations and constraints with regard to issuing bundled management forecasts.

Firms have incentive to cater to investors' information demand and to provide a transparent information environment by voluntarily issuing management forecasts of future earnings (Graham et al. 2005). Therefore, firms exposed to greater information demand are expected to voluntarily disclose more information (Hutton 2005; Chen et al. 2008). To capture this, I include two explanatory variables, the natural log of market value of equity (*LOG_ME*) and the natural log of analysts following (*LOG_AC*), in the selection model. Firms' current disclosure behavior is likely to be related to their previous disclosure record (Hutton 2005; Rogers and Van Buskirk 2011). Hence, the probability of issuing management forecasts along with the current quarter's earnings announcement should be positively associated with the existence of a prior management forecast for the current quarter (*MF_EXIST*) and the existence of a bundled management forecast for the most recent quarterly earnings announcement (*LAG_DBUNDLE*). The selection model also includes prior stock return (*PRIOR_RETURN*) and the proportion of earnings announcements that have met analyst expectations during the prior four quarters (*MEET*). The variables reflect the incentive for firms to issue management forecasts when they perform well in the stock market, or when they have successfully avoided negative earnings surprises (Feng and Koch 2010; Rogers and Van Buskirk 2011). On the other hand, firms are less likely to issue management forecasts if managers face high information uncertainty regarding predicting future earnings. Even though managers are insiders in the company, they may be constrained by the volatility of earnings, and it is costly for managers to forecast frequently and inaccurately. The selection model includes the following variables as proxies for information uncertainty: the absolute value of earnings surprise (*ABS*(*SUE*)); an indicator variable *EABADNEWS* that equals 1 if the current earnings surprise is negative, and 0 otherwise; an indicator variable *LOSS* that equals 1 if the reported earnings number is negative, and 0 otherwise, and analyst forecast dispersion (*AFD*) (Feng and Koch 2010; Rogers and Van Buskirk 2011).

Table 5 reports the results. Firms are more likely to issue bundled management forecasts if there is a prior management forecast for the current quarter's earnings, if there is a bundled management forecast for the most recent quarterly earnings announcement, if the prior stock return is higher, if the firm is larger, if there are more analysts following the firm, or if the firm is more likely to have met analyst estimates during the prior four quarters. The probability of issuing a bundled management forecast is lower when the absolute value of the earnings surprise is larger, when the current earnings announcement conveys bad news, or when the announced earnings number is negative. The results are largely consistent with the univariate analysis in Table 3. The inverse Mills ratios (*IMR*) for all firms are calculated accordingly, using the estimated coefficients. In the second stage, I include the *IMR* in Model (2) and present the results in Table 6.[28]

Under all specifications, the coefficients on *IMR* are statistically significant, justifying the control for endogeneity. The coefficient on *IMR* can be interpreted as the covariance of the error terms of the self-selection model and the post-earnings-announcement drift test. The coefficient is significantly negative when the drift-related variables are not controlled, and becomes significantly positive when the drift-related variables are included in the regressions. The main results are qualitatively similar to those in Table 4. The bundled forecasts with higher *ex ante* accuracy continue to significantly mitigate the post-earnings-announcement drift with a coefficient of −0.022 ($\beta_3 + \beta_4$ with p-value of 0.005) when the *ex ante* accuracy is measured by *Dummy_EstimatedAccuracy*.

Additional Analysis

I examine whether the effect of *ex ante* forecast accuracy on the drift varies with the actual forecast accuracy. Specifically, I compare the coefficients on *DSUE* × *D_BUNDLE* × *Dummy_EstimatedAccuracy* between the bundled forecasts that have higher actual accuracy versus the bundled forecasts that have lower actual accuracy.

When the bundled forecasts have higher actual accuracy (i.e., the actual accuracy is higher than the median), the untabulated results show the coefficient on *DSUE* × *D_BUNDLE* × *Dummy_EstimatedAccuracy* is −0.053 with a t-statistic of −8.12 when the self-selection of issuing bundled forecasts and other drift-related variables are controlled . In contrast, the coefficient is 0.018 with a t-statistic of 2.18 for the bundled forecasts that have lower actual accuracy. This finding suggests that, even though the bundled management forecasts with higher *ex ante* accuracy on average mitigate the drift, the results are driven by the forecasts that have both higher *ex ante* accuracy and higher actual accuracy. Bundled forecasts that have higher *ex ante* accuracy but lower actual accuracy do not mitigate the drift. Instead, such forecasts increase the magnitude of the drift compared to the forecasts with lower *ex ante* accuracy. Taken together, the results suggest that it is necessary for bundled management forecasts to have both high *ex ante* accuracy and high actual accuracy to mitigate the post-earnings-announcement drift.

Robustness Checks

This section tests the robustness of the preceding inferences. First, in many cases, managers forecast not only next quarter's earnings, but also earnings for two, three, four, or more future quarters along with current quarter earnings announcements. These management forecasts may provide incrementally valuable information about the persistence of current earnings into future earnings. To erase this confounding effect, I define *D_BUNDLE* as equal to 1 when an earnings

---

[28] The proportion of earnings announcements meeting analyst expectations in the prior four quarters (*MEET*) is significantly associated with the issuance of bundled management forecasts, but prior literature has not documented the relation between this ratio and the post-earnings-announcement drift. This research design ensures the effectiveness of the two-stage approach, as is suggested by Gong et al. (2011) and Lennox et al. (2012).

All continuous variables are winsorized at the 1 percent and 99 percent levels.

This table presents the results of the probit regression with the dependent variable *D_BUNDLE* that equals 1 if the earnings announcement is bundled with the management forecast of next quarter's earnings, and 0 otherwise. The time period is from the second quarter of year 1997 to the second quarter of year 2007. *MF_EXIST* is an indicator variable that equals 1 if there is a prior management forecast for the current quarter's earnings. The indicator variable *LAG_DBUNDLE* equals 1 if there is a bundled management forecast for the most recent quarterly earnings announcement. *PRIOR_RETURN* is the prior stock return over day −120 to day −1 relative to the earnings announcement date (day 0). *LOG_ME* is the natural log of market value of equity. *LOG_AC* is the natural log of analysts following. *MEET* is the proportion of earnings announcements that have met analyst expectations during the prior four quarters. *ABS(SUE)* is the absolute value of earnings surprise. The indicator variable *EABADNEWS* equals 1 if current earnings surprise is negative, and 0 otherwise. The indicator variable *LOSS* equals 1 if the reported earnings number is negative, and 0 otherwise. *AFD* is the standard deviation of analyst forecasts divided by the stock price at the fiscal quarter end.

announcement is bundled only with the management forecast of next quarter's earnings. The inferences regarding the effect of the *ex ante* accuracy of the bundled management forecasts on the post-earnings-announcement drift remain unchanged.

Second, the main analysis focuses on management forecasts of next quarter's earnings issued within one trading day around the current quarter earnings announcements. I next widen the event window for the definition of bundled management forecasts to include any management forecast of next quarter's earnings made in the period [−10, +1] or [−30, +1] around the current quarter

t-statistics (in parentheses) are based on standard errors clustered on the firm level. Year dummies are included in the regressions.

This table examines the effect of the *ex ante* management forecast accuracy on the post-earnings-announcement drift including the control for self-selection of issuing bundled management forecasts. The sample includes 68,855 quarterly earnings announcements from the second quarter of 1997 to the second quarter of 2007. *IMR* is the inverse Mills ratio calculated for all firms from the estimation results in Table 5. All other variables are defined in Tables 2, 3, and 4.

earnings announcement date (day 0). Investors will incorporate these earlier management forecasts into their reaction to the current quarter earnings announcements as well. When I re-estimate Model (2) by treating these earlier management forecasts as bundled forecasts the results are very similar to those in the main analysis.

Third, in the post-earnings-announcement drift test, the sample period is from the second quarter of 1997 to the second quarter of 2007, which includes the time period before the issuance of Regulation Fair Disclosure (Reg FD). Some earnings announcements might be bundled with private management forecasts, which may also reduce the post-earnings-announcement drift by affecting analyst forecasts, but this effect is not captured, owing to the limited coverage of the First Call CIG database before the issuance of Reg FD. Therefore, I next use only the data after the issuance of Reg FD to estimate Model (2a) and get similar results.

Finally, the inferences are unchanged if I define the drift window starting from trading day 2 after the earnings announcement date of Quarter t and ending on trading day −2 relative to the earnings announcement date of Quarter $t+1$, or a 60-day drift window, as in Liang (2003).

V. CONCLUSION

The under-reaction explanation for the post-earnings-announcement drift argues that investors do not fully understand the implications of current earnings for future earnings, and that this under-reaction is corrected at future earnings announcement dates. I examine a prediction of the under-reaction explanation by investigating whether bundled management forecasts, conditional on their *ex ante* accuracy, mitigate the post-earnings-announcement drift. Using an estimated *ex ante* forecast accuracy measure that is based on forecast ability, forecast difficulty, and forecast environment, I find that bundled management forecasts mitigate the post-earnings-announcement drift when the forecasts have higher estimated accuracy. Additional analysis suggests that this finding is driven by the bundled forecasts that have both higher *ex ante* accuracy and higher actual accuracy.

By analyzing the effect of bundled management forecasts and their *ex ante* accuracy on the post-earnings-announcement drift, this paper adds to the evidence supporting the under-reaction explanation for the drift and complements previous papers that focus on the roles of conference calls and responsive analysts surrounding the earnings announcement dates. Future study may investigate the effect of other information sources on the post-earnings-announcement drift and provide more evidence to explain the existence of the drift.

BOOK REVIEWS

Stephen A. Zeff, Editor

Editor's note: Two copies of books for review should be sent to the Book Review Editor: Stephen A. Zeff, Rice University, Jesse H. Jones Graduate School of Business, 6100 Main St., Houston, TX 77005. The policy of The Accounting Review is to publish only those reviews solicited by the Book Review Editor. Unsolicited reviews will not be accepted.

VIVIEN BEATTIE, STELLA FEARNLEY, and TONY HINES, *Reaching Key Financial Reporting Decisions: How Directors and Auditors Interact* (Chichester, West Sussex, U.K.: John Wiley & Sons, 2011, ISBN 978-0-470-74874-9, pp. xxii, 362).

This book explores how chief financial officers (CFOs), audit committee chairs, and audit engagement partners resolve issues that have given rise to interactions, discussions, or negotiations, between two of these three participants. It is a follow-up of *Behind Closed Doors* (Beattie et al. 2001), which received the Deloitte/American Accounting Association's Wildman Medal in 2007. The book provides an update of the 1999 results in the 2007/2008 U.K. regulatory environment that, as the U.S. one, has undergone significant change since 1999. The book consists of two parts.

The authors present these changes in Chapter 2. After reading the book, I understand why they do it so early in the book. As shown in their updated model of financial reporting interaction, the national regulatory regime now has a significant influence on the interaction outcomes. As in many other jurisdictions, the enforcement regime is now characterized by an increased review of company accounts and inspection of audits of public companies, which has greatly increased the risk of companies and auditors. Also, more specific to the U.K. is the adoption of IFRS and the International Standards on Auditing (ISAs) in 2005. Whereas, for a North American, these standards are often considered as principle-based and requiring the application of judgment, for many of the study's participants these standards are considered as rule-based and reducing the need for judgment.

The research method is identical to that of Beattie et al.(2001): a two phases, mixed-method approach. The first phase consists of a survey of 498 chief financial officers, audit committee chairs, and audit partners of domestic, officially listed U.K. companies. The research instrument used is a combination of closed-form and open questions on a variety of topics, including factors affecting audit quality, the impact of a range of recent changes in the U.K. regulatory framework on their working practices, and their recent experience with discussions and negotiations on 35 financial statement issues. In Chapter 3, the authors provide a summary of the results regarding the top ten issues. While the method is mixed, the significance accorded to the survey in this book is marginal: it is utilized mainly to select the ten companies used for the second phase of the study. Mixing of the data from the two methods (Creswell 2009) is chiefly at the data analysis stage, where survey data are used to support the representativeness of the interactions studied in the company cases.

The second phase of the study consists of a multiple cases study. For the nine company cases, the authors interviewed the CFOs, audit committee chairs, and audit partners regarding the relationship between the three parties and the issues that had given rise to interactions. The remainder of the book is built upon these nine case studies. In conformity with Yin (2003), the authors analyze each case separately, perform a cross-case analysis, and update/modify the model developed in Beattie et al. (2001).

Part II of the book, comprising nine chapters, one for each case, presents the findings. Each chapter follows the same structure. First, there is a descriptive part, presenting background information and interviewees' views about the corporate governance, and, for each interaction issue, the process of interaction and its resolution as perceived by the interviewees. Numerous quotations are provided to exemplify the interviewees' views. The second part of the chapter provides the authors' analysis of the case where, for each interaction, the authors analyze how each was resolved.

Reading each case is very interesting; it provides the reader with information that normally stays behind "closed doors." The advantage of a book, compared to a journal article, is that there is more space to provide detailed information about the cases. With approximately 30 pages per case, the reader has a good understanding of each case. Even then, sometimes I wanted to know more about the interaction issues. Fortunately, more detailed information about one interaction issue is available in Beattie et al. (2011).

The last part of the book presents the cross-case analysis of the 50 interactions using the framework developed in Beattie et al. (2001).[1] They find that the key influence on the interaction outcomes has changed significantly since the previous study. The influence of the general company/audit firm context and specific context of the interaction is greatly reduced, while the national regulatory regime now has the strongest influence on the interaction (events, strategies, outcomes, and consequences). In the "new" regulatory environment, it appears that the higher threats from various regulatory agencies as seen by the CFO, audit partners, and audit committee chairs encourage compliance with accounting and auditing standards.

As indicated before, the book is a successor to *Behind Closed Doors* (Beattie et al. 2001). Indeed, the authors test and update the model developed in the previous book. Chapter 2 presents a summary of this model. Whether readers need to read *Behind Closed Doors* to understand this new book depends on their interests. If readers are interested in how directors and auditors currently interact in reaching financial reporting decisions, the current book would be self-sufficient. However, if readers are interested in how the process has evolved over time, reading *Behind Closed Doors* would be useful.

This book is an excellent response to the call by Bédard and Gendron (2010) for more research on the process dynamics surrounding audit committees and for researchers to get closer to audit committees, directors, and other participants to collect primary data about processes, power, and influence.

I believe that this book should be on the "must read" list of researchers interested in audit committees and financial reporting, regardless of their research approach. For qualitative researchers, the book not only provides valuable insights into the on-process dynamics in reaching financial reporting decisions, but it is also a textbook example of how a researcher may conduct multiple case studies in accounting and gain access to key individuals in organizations to obtain private information about the financial reporting process. For empirical and experimental researchers, the book provides explanations that could be useful in developing their theoretical framework and raises many issues that could be researched in the future. The book should also be of interest to regulators, auditors, accountants, and students who are interested in the financial reporting process and the impact of recent regulation on this process.

MARK LANG and MARK MAFFETT, *Economic Effects of Transparency in International Equity Markets: A Review and Suggestions for Future Research*, Foundations and Trends® in Accounting (Hanover, MA: now Publishers Inc. 2011, ISBN 978-1-60198-448-7, vol. 5, no. 3, pp. 69).

Starting back in 2006, the series "Foundations and Trends® in Accounting" (http://www.nowpublishers.com/product.aspx?product=ACC) has established a track record of so far producing 17 survey and tutorial monographs on various fields in accounting. Each issue comprises a 50–100 page monograph written by leading researchers on a specific topic. The aim of each issue is to provide "tutorial coverage of subjects, research retrospectives, as well as survey papers that offer state-of-the-art reviews." As such, I would argue that its concept is similar to review articles published in the "Commentary" section in *Accounting Horizons* or the review papers commissioned around every ten years by the *Journal of Accounting and Economics*. In terms of required previous knowledge and based on their length, style of writing, and depth, the Foundations and Trends monographs can be situated somewhere between those long-time established sources. The main target audiences are advanced master's students in specialized programs and, in particular, Ph.D. students and their instructors. The series is open-sourced, and the monographs may be downloaded in pdf format from the aforementioned website, a feature I find very helpful for researchers based outside the U.S. who might (still) be faced with accessibility constraints.

The 69-page booklet by Mark Lang and Mark Maffett on the *Economic Effects of Transparency in International Equity Markets* (No. 16 in the series) is an excellent example of what to expect when reading one of these surveys. Its importance arises from the fact that high-quality summary articles and monographs of international work are still rather rare. There is only one prior article in Foundations and Trends by Mary Barth (2006), focusing on challenges in global standard setting. There was no survey published on international work in *JAE* in their last round of survey articles in 2011 (despite, arguably, there having been significant advances in that literature over the past decade).

Lang and Maffett focus on the economic effects of transparency in international equity markets and, therefore, on a core area within the broader context of the informational role of financial accounting in capital markets. They summarize the field of research in international accounting, which probably had the most impact on the academic community, and on where the major advances have occurred over the past decade. These advances were primarily due to the new insights from the finance literature, the availability of new data sources, and the development of new proxies for economic constructs of interest (such as the implied cost of capital). By contrast, advances on the contracting role of accounting in the international context have been much more modest. As such, the general focus of the survey is well chosen.

The booklet is organized in five chapters and has three major parts: Chapters 1 and 2 explain their working framework and focus, Chapter 3 summarizes the relevant literature falling into that framework, and Chapter 4 discusses challenges and suggests directions of future research. Chapter 5 is a one-page conclusion.

The introduction in Chapter 1 defines transparency and lays out how the authors understand "transparency" in what follows. It outlines clearly what the book is about (i.e., capital market consequences of transparency) and which related aspects are excluded from the survey (e.g., determinants of transparency). Next, it describes the core advantages of studying the research questions on transparency and capital market consequences in an international, cross-country setting: (i) there is larger variation in transparency internationally than for U.S. firms, (ii) there is cross-country variation in institutions that have been shown to shape financial reporting practice, and, thus, (iii) firms in the international context face more significant trade-offs in determining their optimal level of transparency.

Also in Chapter 1, the authors set up their framework under which they review the literature. The survey is structured around a standard discounted cash flow model (DCF), which illustrates possible drivers through which transparency may affect equity value: either through expected cash flows (resource allocation) in the numerator of the valuation equation, or alternatively through the denominator and a firm's discount rate (required rates of return), or by affecting both drivers simultaneously.

Chapter 2 explains the focus of their survey on studies analyzing equity capital effects. There are more such studies available, and the underlying relation is theoretically well established. In addition, research on other market-traded sources of financing is just emerging. The chapter also explains that multi-country settings potentially provide more power (as opposed to single-country settings, in the U.S. or elsewhere). Again, cross-country studies offer a much wider range of firm-level disclosure quality than in the U.S. as well as variation in disclosure regulation and enforcement. In addition, these settings allow researchers to study interactive effects and to judge the robustness of U.S. results when applied to multiple other countries. Such studies may also shed light on the discussion on whether reporting standards and reporting incentives are complements or substitutes, a discussion that has emerged recently.

The remainder of Chapter 2 is spent on discussing different ways of measuring transparency in an international setting: analyzing (i) the properties of earnings (e.g., smoothing, discretionary accruals, earnings targets, timely loss recognition), (ii) accounting regime choice (e.g., IFRS adoption), (iii) auditor choice, (iv) the properties of analyst forecasts, and (v) combinations of individual measures ("aggregate measures"). Note that all of these approaches can technically be applied to an international setting because they utilize information available in databases with global coverage (e.g., Compustat Global, Thomson Reuters Worldscope, Bureau van Dijk Osiris).

Chapter 3 represents the core literature review chapter. It summarizes available theory and evidence on the effects of transparency on equity values through two non-exclusive valuation channels: cash flow effects (efficient resource allocation, asset expropriation) in Chapter 3.1 and the effects on firms' discount rates and cost of capital in Chapter 3.2. Within each subchapter, the review is systematically organized into "Theory," "Why international?" and "Evidence." Given that there is more research on the link between transparency and cost of capital, Chapter 3.2 also covers related economic outcome variables beyond the cost of capital per se, for instance, effects on average liquidity or liquidity risk, investor attention, and estimation risk.

Chapter 4 outlines challenges and directions of future research. The authors' conclusion is that research on the topic is "still in its infancy," leaving significant opportunities for future research (p. 53). While I generally agree, I would argue that the "low-hanging fruit," using available global databases and research methods, is nevertheless likely gone. The authors offer three important future directions of research: (i) refining measurement, (ii) establishing more direct linkages, and (iii) identification.

First, refining measurement is important because the available transparency measures are "fairly ad hoc and noisy" (p. 54). I couldn't agree more. In fact, this is an area where accounting researchers need to bring in more of their expertise and comparative advantage. Also note that the transparency measures summarized by Lang and Maffett are almost entirely proxies developed in a U.S. context, which are usually simplistically applied to non-U.S. (GAAP) settings. Although this is a common practice, it will very likely lead to additional measurement error. For example, discretionary accrual models often "forget" to include provisions as a core accrual-type in many non-U.S. accounting regimes. Similarly, it is not even clear what "IFRS adoption" really means when "adopted" at the firm or country level. Finally, the financial statements alone (let alone other information channels) represent much richer information than what is covered in mainstream archival databases. The machine readability of pdf and txt documents or XBRL should lead to new approaches for coding transparency by considering note disclosures or even qualitative information in large samples, reflecting more the subtle effects of language and culture on transparency.

Second, Lang and Maffett note that, while linkages of transparency and economic outcomes have been documented in numerous empirical studies, the interpretation of these results has to be done very carefully. This is because the level of transparency is a choice variable (at the firm or even country level), and therefore an assessment of causality is difficult. Related challenges are the possibility of reverse causality or omitted correlated variables. Thus, as they suggest, we need to work harder on identification and on finding settings that allow for a clean identification strategy. That insight is important and goes beyond international work, because journal editors have become much more demanding when attributing a detected statistical correlation to a theorized economic relation.

In summary, and unsurprisingly, given that Mark Lang has been a key contributor to the international literature for decades, the booklet is an excellent and cohesive overview on the topic, covering most of the relevant work from the accounting, finance, and economics literatures. The comprehensiveness and balance of the survey suffers only slightly due to a natural bias toward the authors' own work, a fact they openly acknowledge (see footnote 2, p. 1). Noteworthy and, in fact, very important is that they put forward a very clear explanation for "Why international?" and consider this issue so important that they cover this question convincingly in every subchapter. If every research project using non-U.S. data would be so clear and honest in asking and answering this question, a lot would be gained for accounting research in general and for a more efficient allocation of research resources around the world.

I would like to comment on a few other positions that the authors take. First, to my taste, there is a bit too much focus on cross-country, or more specifically, "around the world" studies. Note that these studies have unique disadvantages such that country-level institutional variables are highly correlated, the chance of omitted correlated variables bias is high (there is a reason why the institutions are set up in the way they are), and they assume equal informational efficiency across capital markets. Single-country (or -setting) studies may offer more controlled experiments and thus a cleaner identification strategy. In addition, proprietary data to establish a more direct causality in an empirical research design are more likely to become available in a single foreign country setting than simultaneously for many countries around the world. My personal prediction is that we will see more focused single country studies in the near future, offering a unique feature of the accounting system, institution, or market, allowing for a cleaner identification strategy. See, e.g., Giroud et al. (2012) for an illustrative example on unexpected snow in Austrian ski hotels and effects on leverage in the recent finance literature.

Second, I would like to put even more emphasis on analyzing potential *channels* (measurement, disclosure type, content, and form) through which *financial accounting* may affect transparency and ultimately economic outcomes. Despite many decades of work, it is still unclear how specific information channels in financial reporting relate to each other. In the end, we are *accounting* researchers, and much of the content of financial reports of international firms beyond the core summary financials is still largely unexplored territory.

Third, to some extent I missed a discussion on how differences in competing *financial reporting regimes* (beyond local GAAP vs. IFRS) affect transparency in capital markets. There is not much space devoted in the booklet to actual financial reporting issues. I like to note that the global move to IFRS comes at a cost for researchers in that it removes differences across GAAP regimes, which will make an analysis of economic consequences of different measurement basis or disclosure requirements even more challenging in the future.

Finally, the title suggests a survey on "Economic Effects of Transparency in International Equity Markets." However, another important and emerging field of research on the economic consequences of transparency is the macro-level effects on economic growth and financial stability (which, ultimately, will be reflected in a country's equity values). This topic has been of long-time interest in banking supervision and regulation (e.g., third pillar of Basel II), and has recently gained momentum in academic research due to the financial crisis.

In sum, this booklet is a "must read" for any Ph.D. student interested in international work and is suggested background reading for Ph.D. courses in accounting with an emphasis on research using non-U.S. data. To get an even more comprehensive picture, this reading could be complemented by other recent surveys summarizing institutional accounting (e.g., Hail et al. 2011) and IFRS literature (e.g., Pope and McLeay 2011), and related fields of international work where most other advances have occurred over the past decade.

CAPSULE COMMENTARY

By the Book Review Editor

ROBERT H. PARKER, STEPHEN A. ZEFF, and MALCOLM ANDERSON, *Major Contributors to the British Accountancy Profession: A Biographical Sourcebook* (Edinburgh, Scotland, U.K.: The Institute of Chartered Accountants of Scotland, 2012, ISBN 978-1-904574-85-9, pp. 137).

This is a successor to Robert H. Parker's compilation of obituaries that was published in 1980 by Arno Press. But this edition reproduces obituaries, profiles, and interviews with "major contributors" to the British accounting profession, while the earlier volume was confined to British accountants. This book reports on 37 important figures who died between 1941 and 2010, and the coverage includes professional accountants, academics, accountants in industry, editors of professional and academic journals, librarians, executives in professional institutes, and public servants.

The authors supply a lengthy introduction in which they comment on the roles played by the major contributors as well as on the changing scene in the British accounting profession during the past three decades. In a supplement, they supply references to other sources of biographical information about the individuals treated in the book.

As with other research monographs published by the Institute of Chartered Accountants of Scotland, this volume may be downloaded without charge from the Institute's website (http://icas.org.uk).

EDITORIAL POLICY AND STYLE INFORMATION

EDITORIAL POLICY

According to the policies set by the Publications Committee (which were endorsed by the Executive Committee and were published in the *Accounting Education News*, June 1987), *The Accounting Review* "should be viewed as the premier journal for publishing articles reporting the results of accounting research and explaining and illustrating related research methodology. The scope of acceptable articles should embrace any research methodology and any accounting-related subject, as long as the articles meet the standards established for publication in the journal ... No special sections should be necessary. The primary, but not exclusive, audience should be—as it is now—academicians, graduate students, and others interested in accounting research."

The primary criterion for publication in *The Accounting Review* is the significance of the contribution an article makes to the literature. Topical areas of interest to the journal include accounting information systems, auditing and assurance services, financial accounting, management accounting, taxation, and all other areas of accounting, broadly defined. The journal is also open to all rigorous research methods.

The efficiency and effectiveness of the editorial review process is critically dependent upon the actions of both authors submitting papers and the reviewers. Authors accept the responsibility of preparing research papers at a level suitable for evaluation by independent reviewers. Such preparation, therefore, should include subjecting the manuscript to critique by colleagues and others and revising it accordingly prior to submission. The review process is not to be used as a means of obtaining feedback at early stages of developing the research.

Reviewers and editors are responsible for providing constructive and prompt evaluations of submitted research papers based on the significance of their contribution and on the rigor of analysis and presentation.

MANUSCRIPT PREPARATION AND STYLE

The Accounting Review's manuscript preparation guidelines follow *The Chicago Manual of Style* (15th ed.; University of Chicago Press). Another helpful guide to usage and style is *The Elements of Style*, by William Strunk, Jr., and E. B. White (Macmillan). Spelling follows *Webster's Collegiate Dictionary*.

Format

1. All manuscripts should be formatted in 12-point font on 8 1/2 × 11″ paper and should be double-spaced, except for indented quotations.
2. Manuscripts should be as concise as the subject and research method permit, generally not to exceed 7,000 words.
3. Margins should be at least one inch from top, bottom, and sides.
4. To promote anonymous review, authors should not identify themselves directly or indirectly in their papers or in experimental test instruments included with the submission. Single authors should not use the editorial "we".
5. A cover page should show the title of the paper, all authors' names, titles and affiliations, email addresses, and any acknowledgments.
6. The American Accounting Association encourages use of gender-neutral language in its publications.
7. Experimental studies using human subjects should contain a footnote affirming that approval has been granted by the institution where the experiment took place.
8. Headings should be arranged so that major headings are centered, bold, and capitalized. Second-level headings should be flush left, bold, and both uppercase and lowercase. Third-level headings should be flush left, bold, italic, and both uppercase and lowercase. Fourth-level headings should be paragraph indent, bold, and lowercase. Headings and subheadings should not be numbered. For example:

A CENTERED, BOLD, ALL CAPITALIZED, FIRST-LEVEL HEADING

A Flush Left, Bold, Uppercase and Lowercase, Second-Level Heading

A Flush Left, Bold, Italic, Uppercase and Lowercase, Third-Level Heading

A paragraph indent, bold, lowercase, fourth-level heading. Text starts . . .

Pagination: All pages, including tables, appendices and references, should be serially numbered. Major sections should be numbered in Roman numerals. Subsections should not be numbered.
Numbers: Spell out numbers from one to ten, except when used in tables and lists, and when used with mathematical, statistical, scientific, or technical units and quantities, such as distances, weights and measures. For example: three days; 3 kilometers; 30 years. All other numbers are expressed numerically.

Percentages and Decimal Fractions: In nontechnical copy use the word percent in the text; in tables and figures, the symbol % is used.

Hyphens: Use a hyphen to join unit modifiers or to clarify usage. For example: a cross-sectional equation; re-form. See *Webster's* for correct usage.

Keywords: The abstract must be followed by at least three keywords to assist in indexing the paper and identifying qualified reviewers.

Abstract/Introduction

An Abstract of about 100 words (150 maximum) should be presented on a separate page immediately preceeding the text. The Abstract should concisely inform the reader of the manuscript's topic, its methods, and its findings. The Keywords statement should appear immediately below the Abstract. The text of the paper should start with a section labeled "I. Introduction," which provides more details about the paper's purpose, motivation, methodology, and findings. Both the Abstract and the Introduction should be relatively nontechnical, yet clear enough for an informed reader to understand the manuscript's contribution. The manuscript's title, but neither the author's name nor other identification designations, should appear on the Abstract page.

Tables and Figures

The author should note the following general requirements:

1. Each table and figure (graphic) should appear on a separate page and should be placed at the end of the text. Each should bear an Arabic number and a complete title indicating the exact contents of the table or figure. Tables and figures should define each variable. The titles and definitions should be sufficiently detailed to enable the reader to interpret the tables and figures without reference to the text.
2. A reference to each graphic should be made in the text.
3. The author should indicate where each graphic should be inserted in the text.
4. Graphics should be reasonably interpreted without reference to the text.
5. Source lines and notes should be included as necessary.
6. When information is not available, use "NA" capitalized with no slash between.
7. Figures must be prepared in a form suitable for printing.

Equations: Equations should be numbered in parentheses flush with the right-hand margin.

DOCUMENTATION

Citations: Within-text citations are made using an author-year format. Cited works must correspond to the list of works listed in the "References" section. Authors should make an effort to include the relevant page numbers in the within-text citations.

1. In the text, works are cited as follows: author's last name and year, without comma, in parentheses. For example: one author, (Berry 2003); two authors, (Fehr and Schmidt 2003); three or more authors, (Dechow et al. 1998); more than one work cited, (Cole and Yakushiji 1984; Dechow et al. 1995; Levitt 1998); with two works by the same author(s), (Nelson 2003, 2005).
2. Unless confusion would result, do not use "p." or "pp." before page numbers. For example, (Dechow and Dichev 2002, 41–42).
3. When the reference list contains two or more works by the same author (as the only author or first of two or more authors) published in the same year, the suffix a, b, etc., is appended to the date in the within-text citations and in the "References" section. For example, (Johansson 2004a, 2004b, 2004c; Baiman and Rajan 2002a, 2002b; Dhaliwal et al. 2005a, 2005b).

4. When the author's name is mentioned in the text, it need not be repeated in the citation. For example: "Cohen et al. (2005) provide ..."
5. Citations to institutional works should use acronyms or short titles where practicable. For example: (NCFFR, The Treadway Commission 1987).
6. If the paper refers to statutes, legal treatises, or court cases, citations acceptable in law reviews should be used.

Reference List: Every manuscript must include a "References" section that contains only those works cited within the text. Each entry should contain all information necessary for unambiguous identification of the published work. Use the following formats (which follow *The Chicago Manual of Style*):

1. Arrange citations in alphabetical order according to the surname of the first author or the name of the institution or body responsible for the published work.
2. Use authors' initials instead of proper names.
3. For two or more authors, separate authors with a comma, including a comma before "and" (Dechow, P. M., R. Sloan, and A. Sweeney).
4. Date of publication follows the author's (authors') name(s).
5. Titles of journals or newspapers should not be abbreviated.

Sample entries are as follows:

Baiman, S., and M. Rajan. 2002a. The role of information and opportunism in the choice of buyer-supplier relationships. *Journal of Accounting Research* 40 (2): 247–278.

Footnotes: Footnotes are not used for documentation. Textual footnotes should be used only for extensions and useful excursions of information that if included in the body of the text might disrupt its continuity. Footnotes should be inserted using the "footnote" or "endnote" feature of the word processing software which will automatically number the footnotes throughout the manuscript with superscript Arabic numerals.

SUBMISSION OF MANUSCRIPTS

Authors should note the following guidelines for submitting manuscripts:

1. Manuscripts currently under consideration by another journal or publisher should not be submitted. The author must state upon submission that the work is not submitted or published elsewhere.
2. For manuscripts reporting on field surveys or experiments: If the additional documentation (e.g., questionnaire, case, interview schedule) is sent as a separate file, then all information that might identify the author(s) must be deleted from the instrument.
3. New manuscripts must be submitted through the Manuscript Submission and Peer Review System, located at http://accr.allentrack.net. The site contains detailed instructions regarding the preparation of files for submission. Revisions of manuscripts originally submitted before June 1, 2011 should be sent via email to the senior editor, John Harry Evans III, at tar@katz.pitt.edu. Please submit separate files for (1) the manuscript's title page with identifying information (not forwarded to reviewers), (2) the manuscript with title page and all other identifying information removed, and (3) any necessary supplemental files, such as experimental instructions and/or response memoranda on invited revisions.
4. A nonrefundable submission fee is required unless explicitly waived by the editor for invited revisions of previous submissions. The submission fee in U.S. funds is $200.00 for members and $400.00 for nonmembers of the AAA payable by credit card (VISA or MasterCard only). The payment form is available online at: https://aaahq.org/AAAforms/journals/tarsubmit.cfm. If you are unable to pay by credit card or have any questions, please contact the AAA Member Services Team at (941) 921-7747 or info@aaahq.org.
5. Revisions must be submitted within 12 months from the decision letter inviting a revision.

COMMENTS

The Accounting Review welcomes submissions of comments on previous *TAR* articles. Comments on articles previously published in *The Accounting Review* will generally be reviewed by two reviewers, usually including an author of the original article (to assist the editor in evaluating whether the submitted comment represents the prior article accurately) and an additional reviewer who is independent of the original article. If a comment is accepted for publication, the original author will generally be invited to reply. All other editorial requirements, as enumerated above, apply to proposed comments.

POLICY ON REPRODUCTION

An objective of *The Accounting Review* is to promote the wide dissemination of the results of systematic scholarly inquiries into the broad field of accounting.

Permission is hereby granted to reproduce any of the contents of the *Review* for use in courses of instruction, as long as the source and American Accounting Association copyright are indicated in any such reproductions.

Written application must be made to the American Accounting Association, 5717 Bessie Drive, Sarasota, FL 34233-2399, for permission to reproduce any of the contents of the *Review* for use in other than courses of instruction—e.g., inclusion in books of readings or in any other publications intended for general distribution. In consideration for the grant of permission by the *Review* in such instances, the applicant must notify the author(s) in writing of the intended use to be made of each reproduction.

Except where otherwise noted in articles, the copyright interest has been transferred to the American Accounting Association. Where the author(s) has (have) not transferred the copyright to the Association, applicants must seek permission to reproduce (for all purposes) directly from the author(s).

POLICY ON DATA AVAILABILITY

The AAA's Executive Committee policy (originally adopted in 1989, and amended in 2009) is that the objective of the Association-wide journals (*The Accounting Review, Accounting Horizons, Issues in Accounting Education*) is to provide the widest possible dissemination of knowledge based on systematic scholarly inquiries into accounting as a field of professional research, and educational activity. To fulfill this objective, authors are encouraged to make their data available for use by others in extending or replicating results reported in their articles.

SEPTEMBER 2012 PLACEMENT ADS

The deadline for free position ads to be included in this section of *The Accounting Review* is two months prior to the desired publication in the January, March, May, July, September, or November issues. Position ads, which are free with the purchase of a job posting in the AAA Career Center, should provide all relevant information about the available positions and must include contact information or application instructions for interested candidates. For more information on how to purchase a job posting in the Career Center, or for up-to-date, detailed information about the placement listings in this issue, please go to the AAA website at http://aaahq.org and click on "Career Center," or call our office at 941-921-7747.

TEREX CORPORATION (the Company) is a *Fortune* 500 Company and a global business leader that manufactures a broad range of equipment for the construction, infrastructure, quarrying, mining, shipping, transportation, refining, and utility industries. The Company operates in four business segments throughout the world: Aerial Work Platforms, Construction, Cranes, and Materials Processing. Terex offers a complete line of financial products and services to assist in the acquisition of Terex equipment through Terex Financial Services. The Staff Accountant position is a part of the Terex Utilities Division. Terex Utilities is a truck equipment, final-stage manufacturer of digger derricks, aerial devices, and associated equipment for the utility industry, municipals, telecommunications, tree, and electrical contractor markets. The right candidate will be an energetic experienced professional with excellent communication, organizational, and multi-tasking skills. The candidate should thrive in a changing and dynamic environment and possess the ability to address and resolve integration and customer issues. This is an excellent opportunity for someone who is looking to grow within an organization and become a valued member of our team. This position is a full-time position located in Watertown, SD. Compensation is commensurate with experience and includes benefits such as paid vacation/sick time, medical/dental/vision, and 401K. Relocation is also available for this position. To apply please visit http://www.terex.com/careers and search for Staff Accountant.

FUDAN UNIVERSITY, School of Management, Accounting Department invites applications for Associate Professor/Full Professor. Interested candidates please submit a *cv* and recent research papers. In addition, three reference letters should be sent directly to: Ms. Zhou Yan, Faculty Development Office, School of Management, 670 Guo Shun Road, Shanghai 200433; Phone: 86-21-65642410; Fax: 86-21-65654523; Email: hrfdms@fudan.edu.cn; Website: http://www.fdsm.fudan.edu.cn

SAN JOSE STATE UNIVERSITY invites applications for two tenure-track faculty positions contingent on budget approval. If approved, the applicant start date is August 2013. The available accounting positions are at the Full, Associate, or Assistant Professor rank for Financial, Managerial Accounting/Audit, and Taxation or a temporary Visiting Professor in Audit or Taxation. The candidate must have demonstrated versatility in subject matter competencies and pedagogy. The teaching assignment is at both graduate and undergraduate levels including traditional and accelerated formats. The positions are subject to budget approval. The minimum credential requirement is ABD for tenure-track and visiting appointments. Strong preference will be given to candidates who hold a Ph.D. from an AACSB-accredited university. Applicants must be academically qualified based on SJSU CoB policy. The application deadline is November 11, 2012 or until the position is filled. Send application letter, *vita*, teaching evaluations, and three letters of reference to: Dr. Janis Zaima, Chair, Accounting & Finance Department, College of Business, San Jose State University, One Washington Square, BT850, San Jose, CA 95192-0066; Phone (408) 924-3490; Email: Janis.Zaima@sjsu.edu. Interviews at AAA may be scheduled with Dr. Zaima. SJSU is an Equal Opportunity/Affirmative Action Employer committed to the core values of inclusion, civility, and respect for each individual.

SAN JOSE STATE UNIVERSITY invites applications for two tenure-track faculty positions in Accounting and Tax, contingent on budget approval. If approved, the applicant start date is August 2013. The available tax positions are at Full, Associate, or Assistant Professor ranks or a combination of J.D./CPA, or J.D./M.S.T., or J.D./L.L.M.-tax or a temporary Visiting Professor. The candidate must have demonstrated versatility in subject matter competencies and pedagogy. The teaching assignment is at both graduate and undergraduate levels including traditional and accelerated formats. The positions are subject to budget approval. The minimum credential requirement is ABD for tenure-track and visiting appointments. Strong preference will be given to candidates who hold a Ph.D. from an AACSB-accredited university. Applicants must be academically qualified based on SJSU CoB policy. The application deadline is November 11, 2012 or until the position is filled. Send application letter, *vita*, teaching evaluations, and three letters of reference to: Dr. Janis Zaima, Chair, Accounting & Finance Department, College of Business, San Jose State University, One Washington Square, BT850, San Jose, CA 95192-0066; Phone: (408) 924-3490; Email: Janis.Zaima@sjsu.edu. Interviews at AAA may be scheduled with Dr. Zaima. SJSU is an Equal Opportunity/Affirmative Action Employer committed to the core values of inclusion, civility, and respect for each individual.

DEPAUL UNIVERSITY, School of Accountancy seeks to fill a tenure-track faculty appointment in accountancy and MIS. Teach graduate and undergraduate courses in accounting. Present and deliver lectures. Review and grade assignments. Perform academic advising of students. Conduct research in the field of Accounting. Ability and interest in teaching capstone courses in accounting theory and research required. To apply, go to: http://facultyopportunities.depaul.edu/applicants/Central?quickFind=50892

UNIVERSITY OF DAYTON (UD), Department of Accounting seeks candidates for a tenure-track Asst/Assoc position beginning 08/16/2013. All areas considered; prefer systems, auditing, tax, and those who teach in multiple areas. Must meet, and be able to maintain, AACSB requirements for AQ. Must be ABD; preference given to Ph.D./D.B.A. from an AACSB and/or EQUIS institution, with relevant experience. The University of Dayton, founded in 1850 by the Society of Mary, is a top ten Catholic research university. The University seeks outstanding, diverse faculty and staff who value its mission and share its commitment to academic excellence in teaching, research, and artistic creativity, the development of the whole person, and leadership and service in the local and global community. To attain its Catholic and Marianist mission, the University is committed to the principles of diversity, inclusion, and affirmative action and to equal opportunity policies and practices. We act affirmatively to recruit and hire women, traditionally under-represented minority groups, people with disabilities, and veterans. For a complete listing of qualifications and to apply go to: http://jobs.udayton.edu/applicants/Central?quickFind=53300. Review of applications will begin 07/02/2012 and continue until filled. http://www.udayton.edu/business/accounting/index.php.

BOCCONI UNIVERSITY, Accounting Department has tenure-track positions available at the level of Assistant/Associate Professor. Courses are to be taught in English. Knowledge of Italian is not required. Candidates should have a completed (or close to be completed) Ph.D. with focus on Accounting. Applicants are expected to have a demonstrated potential for, or history of, outstanding research and strong teaching skills. Applicants should send their resume, samples of research, and three letters of reference using the online form at: http://www.unibocconi.eu/jobmarket. Applications will be considered until October 15, 2012. For further academic information please contact: Prof. Sasson Bar-Yosef (sasson.baryosef@unibocconi.it) or Prof. Annalisa Prencipe (annalisa.prencipe@unibocconi.it).

LA SALLE UNIVERSITY invites applications for one tenure-track Assistant Professor beginning August 2013 (subject to budget approval). Candidates must have a doctoral degree in accounting from an AACSB-accredited university. ABDs nearing completion will be considered. Candidates should demonstrate research skills and a strong interest in undergraduate and graduate teaching. Review of applications will begin June 1, 2012 and continue until the position is filled. La Salle University is a Roman Catholic University in the tradition of the De La Salle Christian Brothers and welcomes applicants from all backgrounds who can contribute to our unique educational mission. For further information, please visit our website at: http://www.lasalle.edu. Submit electronically a letter of application, *curriculum vitae*, and contact information for three references to: Dr. Mary Jeanne Welsh, Chair, Accounting Department, La Salle University, 1900 W. Olney Avenue, Philadelphia, PA 19141: Email: welsh@lasalle.edu. AA/EEO.

UNIVERSITY OF BALTIMORE, Merrick School of Business invites applications for a faculty member to start during the 2013–2014 academic year. Individuals with research and teaching interests in auditing and a CPA certification are preferred. Employment offer is contingent on position funding. The Merrick School of Business is AACSB International accredited and is nationally recognized by *U.S. News & World Report* as one of the country's best undergraduate business programs and one of the country's best part-time M.B.A.s in 2012. UB also ranks # 1 in terms of accounting leadership in Baltimore. Qualifications: Successful candidates will have a doctoral degree in accounting from an AACSB-accredited university. Applicants with the doctoral degree are preferred although ABDs will be considered. Experienced applicants are expected to display a strong research record; new Ph.D.s and ABDs must demonstrate potential for research productivity. Salary is competitive and commensurate with experience. Document review will begin immediately. Applicants should electronically submit a letter of interest including a statement of teaching and research philosophy, a *curriculum vitae*, recent teaching evaluations, and any additional supporting materials. Three letters of recommendation highlighting teaching ability and experience should be sent to: Prof. Phil Korb at pkorb@ubalt.edu. http://www.ubalt.edu. EOE/ADA/AA

DREXEL UNIVERSITY, LeBow College of Business, Department of Accounting and Taxation invites applications for two Assistant positions starting September 1, 2013. Applicants should have earned their doctorates before the beginning of the contract period. While all areas will be considered, preference will be given to candidates with interests in Financial and Managerial Accounting. The LeBow College of Business offers an undergraduate accounting degree, an M.S. in Accounting, and a Ph.D. with an accounting emphasis. The Department has a rich tradition of interfacing with the Philadelphia business community through our well-established undergraduate co-op program and an active Accounting Advisory Board. Positions will remain open until filled. Send a letter of application, *vita*, and other supporting materials electronically to: http://www.drexeljobs.com. Drexel University is an Equal Opportunity/ Affirmative Action Employer and encourages applications from women, members of minority groups, disabled individuals, and veterans.

WASHINGTON & LEE UNIVERSITY, Department of Accounting invites applications for a tenure-track position at the Assistant or Associate level beginning in Fall 2013. Washington & Lee is a small, private, highly selective university located in the scenic Shenandoah Valley. Its Williams School of Commerce, Economics, and Politics has been AACSB-accredited since 1927. Job Qualifications: Applicants should have a doctorate or be close to completion and have teaching interests in Auditing. In addition to requiring high-quality teaching, applicants are expected to conduct research publishable in peer-reviewed journals. To support research, the School subscribes to several popular databases available through WRDS. Application Procedure: Candidates should electronically submit a cover letter, *curriculum vitae*, evidence of teaching effectiveness and scholarly work to: http://jobs.wlu.edu/postings/1198. Specific questions about the position should be sent via email to: Dr. Afshad Irani (irania@wlu.edu). Washington & Lee University is an Equal Opportunity/Affirmative Action Employer.

LOUISIANA TECH UNIVERSITY, School of Accountancy seeks applications for Assistant or Associate Professor for Fall 2013 appointment. Accounting doctorate is essential, with a strong preference for candidates with accounting certification and a preference for auditing or tax. An established publication record of discipline-based scholarship in high-quality journals is preferred. Position requires upper-division and graduate-level teaching, publishing discipline-based research, and involvement with the accounting doctoral program. Responsibilities could also include teaching an occasional online class. Applicant review continues until position is filled. Salary is competitive. Located 65 miles east of Shreveport and 30 miles west of Monroe, enrollment is around 11,500 students. Please send applications or letters of inquiry to: Thomas J. Phillips, Jr., Director, School of Accountancy, PO Box 10318, Louisiana Tech University, Ruston, LA 71272; Phone: (318) 257-2822; Fax: (318) 257-4253; Email: phillips@latech.edu; Website: http://www.business.latech.edu. EEO/AA/ADA. Women and minorities encouraged to apply. Member of the University of Louisiana System.

SAM HOUSTON STATE UNIVERSITY, College of Business Administration is seeking candidates for a tenure-track Assistant Professor position in the Department of Accounting beginning Fall 2013 (pending budgetary approval). Sam Houston State University has approximately 17,000 students and is located in picturesque Huntsville, Texas, approximately 70 miles north of downtown Houston, with easy interstate highway access to Houston and Bush Intercontinental Airport. The College is AACSB-accredited and has approximately 3,000 majors including over 550 accounting majors. The Department of Accounting has approximately a dozen tenured/tenure-track faculty. Additional information regarding the College of Business Administration and the Department of Accounting can be found at: http://www.shsu.edu/~coba/ or at http://www.shsu.edu/accounting. Candidates must have a Ph.D. or D.B.A. (or ABD near completion) in Accounting from an AACSB-accredited university, be academically qualified under AACSB standards, be highly committed to quality teaching, and exhibit strong potential for successful research and publication. Professional certification is preferred. Interested candidates may contact accounting@shsu.edu. Sam Houston State University is a member of The Texas State University System and is an EEO/AAP employer.

BRADLEY UNIVERSITY, Foster College of Business Administration invites applications and nominations for a tenure-track Assistant Professor position in Accounting. Located in Peoria, IL with 5,000 undergraduate and 1,000 graduate students, Bradley offers the opportunities of a larger university and personal attention of a small private university. The Department of Accounting has separate AACSB accounting accreditation, offers baccalaureate and master's degrees, and is a member of the Institute of Internal Auditor's Internal Audit Education Partnership program. A Ph.D., D.B.A., or near completion with emphasis in accounting is required. Professional certification (CPA, CMA, or CIA) and work experience are desirable. Primary teaching needs are in Auditing, Financial Accounting, and/or Accounting Information Systems. Demonstrated excellence in teaching and scholarly research is required for tenure and promotion. Salary is AACSB competitive. Position is available Fall 2013 with teaching opportunities available at both the undergraduate and graduate levels. Interested applicants should submit a letter of application, current *vita*, transcripts, and contact information for three professional references to: Dr. Mollie Adams, Search Committee Chair, Department of Accounting, Bradley University, Peoria IL 61625: Phone (309) 677-2284; Email: mtadams@bradley.edu. Screening of applications will begin on July 2, 2012, and continue until the position is filled. For additional information, please visit: http://www.bradley.edu. Employment with Bradley University is contingent upon the satisfactory completion of a criminal background check. Bradley University is an Equal Opportunity and Affirmative Action Employer. The administration, faculty, and staff are committed to attracting qualified candidates from underrepresented groups.

RUTGERS, THE STATE UNIVERSITY OF NEW JERSEY, CAMDEN, School of Business is inviting applications for three tenure-track positions at the Assistant Professor level in the areas of audit and managerial accounting with a secondary emphasis in tax or financial accounting. The positions will be available July 2013, subject to final academic and budgetary approval. The Rutgers School of Business, Camden is AACSB-accredited (http://camden-sbc.rutgers.edu), and serves more than 700 undergraduate and 300 M.B.A. students. The Campus is located in southern New Jersey just across the Delaware River from downtown Philadelphia, with easy access to Atlantic City, New York, and Washington, DC. The review process begins immediately and will continue until the positions are filled. The ideal candidate will possess a Ph.D. degree in Accounting and demonstrate the capacity for high-quality research and effective teaching. ABDs who expect to complete their degree before July 2013 will also be considered. The teaching load is two courses (6 credits) per semester. The positions may require some teaching at off-campus locations of the University. To apply, please email your letter of application clearly indicating your qualifications and interests, a copy of your current *vita*, and a copy of your job market paper to: SBCacctgfaculty@camden.rutgers.edu. Rutgers University is an Affirmative Action/Equal Opportunity Employer, and committed to diversity among faculty. Women, under-represented minorities, veterans, and individuals with disabilities are especially encouraged to apply.

UNIVERSITY OF INDIANAPOLIS, Accounting School of Business seeks candidates for an Assistant or Associate Professor for a full-time, nine-month, tenure-track position with a start date of January 2013. The successful candidate will participate in teaching, service, and scholarship as it relates to the field of accounting. The ideal candidate will have a strong record of teaching excellence at the undergraduate level for accounting and nonaccounting majors; the ability to teach introductory financial and managerial accounting; and willingness to teach some evening sections. Experience with accounting information systems is preferred. Earned doctorate in accounting or related business field and proficiency in teaching and knowledge of the accounting field required. ABD candidates may apply. M.B.A./CPA candidates may be considered for a non-tenure-track appointment. Applied scholarship and active participation in the discipline is a plus. Apply electronically at: http: //www.uindy.edu/visitors/hr. The University of Indianapolis is an Affirmative Action/Equal Opportunity Employer and encourages applications from women and minorities.

AUBURN UNIVERSITY, School of Accountancy is seeking to fill one full-time tenure-track Assistant Professor position, contingent upon budget approval, beginning Fall 2013. Job Qualifications: Successful applicants must possess a doctorate in accounting from an AACSB-accredited institution prior to the date of employment. The successful candidate must meet eligibility requirements to work in the U.S. at the time the appointment is scheduled to begin and continue working legally for the proposed term of employment. Excellent communication skills are required. Job Responsibilities: While all areas of teaching and research will be considered, the areas of immediate need are financial and AIS. Candidates must have strong research credentials/potential and will be expected to publish scholarly journals. The faculty member is expected to contribute in instruction, research, and service/outreach/extension. Candidates with professional certification are desired. Application Procedure: Review of applications will begin September 1, 2012 and continue until a qualified candidate is selected and recommended for appointment. Applicants should mail a letter of application, curriculum *vitae*, teaching evaluations, a current working paper or dissertation proposal, and names of three references to: Recruiting Coordinator, 301 Lowder Business Building, Auburn, AL 36849. Materials may also be emailed to: acct@auburn.edu. Auburn University is an Affirmative Action/Equal Opportunity Employer. Minorities and women are encouraged to apply.

KENT STATE UNIVERSITY, Department of Accounting invites applications for a tenure-track position at the Assistant, Associate, or Full Professor level beginning Fall 2013. We are primarily interested in candidates with teaching and research interests in Financial Accounting. Preference will be given to experienced Assistant, Associate, or Full Professors with an established scholarly record. Candidates must have a Ph.D. with a major in accounting or an appropriate related field. Professional certification such as a CPA or CMA is highly desirable. Research will be expected in high-quality, academic refereed journals; service on doctoral students' dissertations will be part of the faculty member's responsibilities. Review of applications will begin immediately and continue until the position is filled. Applicants may contact: Professor Mark Altieri, Chair Faculty Recruiting Committee, Department of Accounting, Kent State University, PO Box 5190, Kent OH 44242-0001; Email: maltieri@kent.edu. Applicants will be required to apply online at: http://jobs.kent.edu and search for posting #990060. AA/EOE.

KENT STATE UNIVERSITY, Department of Accounting invites applications for a tenure-track position at the Assistant, Associate, or Full Professor level beginning fall 2013. We are primarily interested in candidates with teaching and research interests in Cost/Managerial Accounting. Candidates must have a Ph.D. with a major in accounting or an appropriate related field. Professional certification is highly desirable. Research will be expected in high-quality, academic refereed journals; service on doctoral students' dissertations will be part of the faculty member's responsibilities. Candidates for an Associate or Full position must have an established scholarly record. Review of applications will begin immediately and continue until the position is filled. Applicants may contact: Professor Mark Altieri, Chair Faculty Recruiting Committee, Department of Accounting, Kent State University, PO Box 5190, Kent OH 44242-0001; Email: maltieri@kent.edu. Applicants will be required to apply online at: http://jobs.kent.edu and search for posting #998731. AA/EOE.

CLAYTON STATE UNIVERSITY, Morrow, GA has two permanent faculty tenure-track faculty lines in accounting that are expected to be offered and filled beginning August 2013. An AACSB-accredited School with five full-time accounting faculty supporting an undergraduate B.B.A. accounting major and an M.B.A. accounting concentration, we seek Accounting Ph.D.s from AACSB-accredited institutions. Rank of Assistant or Associate is negotiable with salary. CPA and other certification is desirable; 18 graduate hours in finance is also a plus. Our greatest needs in teaching are auditing and tax, but will consider candidate interests in AIS or financial. All accounting faculty are expected to teach accounting principles courses in addition to their interest areas. Opportunities exist for graduate teaching, and research and service requirements are competitive with other AACSB institutions. Our wooded campus of three lakes is located in beautiful suburban Atlanta, GA. To learn more, contact Greg Kordecki, 404-798-0150, gregkordecki@clayton.edu.

MIAMI UNIVERSITY, Department of Accountancy has up to three positions available. Assistant or Associate Professor to teach accounting courses at both the undergraduate and master's level; conduct and publish scholarly research; provide service to the institution, academy, and profession. Required qualifications: A doctorate in accounting or dissertation in process with completion of degree by December 31, 2013. For appointment to rank of Associate Professor requires high-quality teaching and research. Preferred qualifications: Candidates who have primary interest in tax accounting, although applicants interested in any area of accounting will be considered; professional certification (CPA or similar); relevant professional work experience. Employment: Positions are expected to begin August 2013. Both the undergraduate and graduate accounting programs are AACSB-accredited; information about the faculty and curriculum is available at: http://www.sba.muohio.edu. Application Procedure: Submit letter expressing interest in the position, resume, and letters from three references online at: http://www.fsb.muohio.edu/employment/accounting. Online applications only will be accepted. Screening of applications begins September 1, 2012 and will continue until the positions are filled. Women and minorities are encouraged to apply. Miami University is an EOE/AA employer with smoke-free campuses and offers full same-sex domestic partner benefits. Right to Know-Consumer Information at: http://www.miami.muohio.edu/about-miami/publications-and-policies/student-consumer-info/. Hard copy upon request.

TRUMAN STATE UNIVERSITY, School of Business, AACSB-accredited, invites applications for one (1) tenure-track position in accounting (rank depends on qualifications). Talented students and a collegial faculty create an outstanding work environment. Starting date is August 2013, but is negotiable. For more information, please go to: http://provost.truman.edu/positions/ACCT043012Fall_2013.pdf

CORNERSTONE RESEARCH, a leading economics and finance consulting firm specializing in analyzing economic, financial, accounting, and marketing issues, is interested in hiring full-time and summer associates for its offices in Boston, MA, Los Angeles, CA, Menlo Park, CA, New York, NY, San Francisco, CA, and Washington, DC. Cornerstone Research provides an interesting and rewarding work environment. Associates work directly with esteemed faculty experts in a distinctive partnership that combines the strengths of the academic and business worlds. We seek Ph.D. candidates with the ability to apply academic research to real-world issues, present concise explanations of complex analyses, and independently manage projects and junior staff. The ideal candidate will possess a strong empirical background in Financial, Cost, or Auditing, as well as demonstrate excellent interpersonal skills. We also seek experienced candidates for more senior levels. Compensation commensurate with experience. Submit resume, sample research paper, and cover letter that includes a statement describing your interest in economic consulting and your location preferences, resume, and letters of reference at: http://Associatecareer.cornerstone.com. Recruiting Coordinator, AR web page: http://www.cornerstone.com

NORTHERN ILLINOIS UNIVERSITY invites applications for Director of its CPA Review Program. The Director of the NIU CPA Review is the administrator of the credit and noncredit CPA review courses offered through the Department of Accountancy in all formats (live, online, and blended). The Director is expected to teach in the program, recruit, and supervise CPA Review faculty, review and approve materials developed for the program, market the program, recruit and advise program participants, prepare and monitor the annual budget, and represent the Department of Accountancy by interacting with firms, professional organizations, and other universities. Additional information about the CPA Review can be found at http://www.cpareview.niu.edu/. Candidates must have a master's degree in accounting (or an M.B.A. with an accounting specialization) or a bachelor's degree with a minimum of ten years of significant accounting experience in public accounting or industry. All candidates must have at least three to five years with a public accounting firm or a comparable position in industry. In addition, candidates must have a demonstrated record of effective teaching (either at the college level or in professional accounting continuing education) and be a Certified Public Accountant (CPA) licensed to practice in a U.S. jurisdiction. Applicants should send a cover letter, resume, and a summary of any teaching evaluations to: Jim Young, Chair, Department of Accountancy, Northern Illinois University, DeKalb, IL 60115. Review of complete applications will begin on July 31, 2012 and will continue until the position is filled. AA/EEO institution.

The University of Michigan–Dearborn is dedicated to the goal of building a culturally diverse and pluralistic faculty committed to teaching and working in a multicultural environment, and strongly encourages applications from minorities and women. The University of Michigan-Dearborn is an Equal Opportunity/Affirmative Action Employer.

OHIO UNIVERSITY, School of Accountancy invites applications for two tenure-track appointments as Assistant/Associate Professor beginning in August 2013. We are looking for student-friendly, research-active, innovative faculty members, and will consider applicants with teaching and research interests in any area of accounting. All applicants must be academically qualified under AACSB standards, be able to show evidence of the ability to produce quality research and to achieve a record of teaching excellence, and be committed to professional interaction. Ohio University's College of Business and its School of Accountancy are both accredited by the AACSB. The School of Accountancy at Ohio University takes pride in the ongoing success of our problem-based curriculum, our innovative faculty, and our outstanding relationships with the Accounting Profession. Our graduates are heavily recruited by the Big 4 and large regional accounting firms. Ohio University takes pride in its vibrant residential campus that attracts top-quality students. Athens, Ohio, is a quintessential college town and is a family-friendly and culturally rich community located amidst scenic state and national parks just 75 minutes southeast of Columbus, Ohio. Review of applications will begin August 1, 2012 and continue until the position is filled. Please send *vita* and letter of interest directly to Dr. Ann Gabriel, Director of the School of Accountancy at: gabriele@ohio.edu.

ARKANSAS STATE UNIVERSITY (ASU) is recruiting applicants for an Assistant Professor in the department of Accounting. The Assistant Professor will teach accounting classes at the graduate and undergraduate levels, using a variety of delivery methods. The position is housed on the Jonesboro campus. Therefore, visit: https://jobs.astate.edu for detailed information and to apply for position F00616. ASU is committed to creating a productive workplace in which both persons and property are secure. To achieve that goal, background investigations are conducted on all final applicants recommended for employment. ASU is an Equal Opportunity/Affirmative Action Employer with a strong institutional commitment to the achievement of excellence and diversity among its faculty and staff.

UNIVERSITY OF ILLINOIS AT URBANA–CHAMPAIGN, The Department of Accountancy is recruiting faculty for full-time appointments at all ranks. Candidates at advanced ranks must possess a doctoral degree, and candidates for Assistant Professor positions must possess or be near completion of a doctoral degree. Applicants for senior positions should have a strong research record and the ability to participate in doctoral education and curriculum development at the undergraduate and graduate levels. In addition, non-tenure-track Lecturer and Visiting positions are available. Applicants should submit a resume that lists research publications and courses taught. Compensation is competitive and will be commensurate with the appointment level and applicant's record. For full consideration, please create your candidate profile at: http://jobs.illinois.edu and upload your required documents, including cover letter, *curriculum vitae*, teaching statement, research statement, working papers, course evaluations, and the names and email addresses or phone numbers of three professional references. Tenure-track applications should be submitted by January 31, 2013. Visitor and Lecturer applications should be submitted by March 31, 2013. In your cover letter please state which rank you are applying for. For further information please refer to: http://www.business.illinois.edu/accountancy/recruit.html or email: accyrecruiting@business.illinois.edu. Contact: Recruiting Chair, Department of Accountancy, 360 Wohlers Hall, College of Business, University of Illinois, 1206 S. Sixth Street, Champaign, IL 61820. Illinois is an Affirmative Action/Equal Opportunity Employer and welcomes individuals with diverse backgrounds, experience, and ideas who embrace and value diversity and inclusivity. (http://www.inclusiveillinois.edu).

CALIFORNIA STATE UNIVERSITY, SAN BERNARDINO, Department of Accounting and Finance expects to fill a tenure-track faculty position in accounting beginning September 1, 2013, rank open, pending budgetary approval. At the time of appointment, the candidate must have a Ph.D. in accounting or be academically qualified in accounting according to AACSB standards. Industry experience and/or CPA a plus. Candidates at higher ranks are expected to demonstrate excellence in teaching, research, and service. All areas of accounting will be considered, but preference will be given to candidates with expertise in financial accounting, government accounting, and/or taxation. As one of the five departments in the College of Business and Public Administration, which is accredited by AACSB and NASPAA, the Department of Accounting and Finance is seeking AACSB-accreditation for its accounting programs. The successful candidate will be expected to participate in this endeavor, to meet the traditional requirements of excellence in teaching, research, and service, and to support the University's strategic plan, which includes partnership with the community to enhance the social, economic, and cultural conditions of the community and beyond. Salary dependent on qualifications and experience. Possibility to earn additional compensation through summer school teaching. Generous medical, dental, and vision benefits, support for moving expenses, and CalPERS pension. Applications accepted until the position is filled but preferably by July 20, 2012. Submit a *cv* and letter of application to: rchen@csusb.edu as well as to: tsalas@csusb.edu.

UNIVERSITY OF MISSOURI–COLUMBIA, School of Accountancy is seeking applications for a tenure-track faculty position at the Assistant Professor level for Fall 2013. Candidates for the position must have an interest in Auditing, and be committed to high-quality scholarly research. Applications are encouraged from experienced Assistant Professors as well as new Ph.D.s or those nearing completion of their Ph.D. Salary and research support are competitive. Application materials including a letter of interest, *vita*, evidence of teaching competence, and a sample of working papers should be submitted online at: http://hrs.missouri.edu/find-a-job/academic/index.php. Three reference letters should be mailed to: Recruiting Committee, School of Accountancy, University of Missouri, 303 Cornell Hall, Columbia, MO 65211. Early applications are encouraged, and screening will begin October 1, 2012, and continue until the position is filled. The University of Missouri is an Equal Opportunity/Affirmative Action Employer. Applications from minority and women candidates are strongly encouraged for this position. To request ADA accommodations, please contact the University's ADA Coordinator at (573) 884-7278 (V/TTY).

THE UNIVERSITY OF OKLAHOMA, John T. Steed School of Accounting invites applications for the position of Assistant Professor. Candidates must possess an appropriate doctorate or be near completion. Candidates must have academic training that indicates the potential for significant high-quality academic research. The anticipated appointment date is August 15, 2013. All qualified individuals are encouraged to submit application materials to: Jan Nelson, Managerial Associate, Steed School of Accounting, Price College of Business, University of Oklahoma, 307 W. Brooks, AH 200, Norman, OK 73019-400; Email: jnelson@ou.edu; Phone: (405) 325.4223; Fax: (405) 325.7348. For questions, please contact the search committee chair, Wayne Thomas (wthomas@ou.edu). The screening of applications will begin immediately. Applications will be accepted until the position is filled. The University of Oklahoma is an Equal Opportunity/Affirmative Action Employer. Women and Minorities are encouraged to apply.

VIRGINIA POLYTECHNIC INSTITUTE AND STATE UNIVERSITY, Department of Accounting and Information Systems, Pamplin College of Business seeks to fill one or more tenure-track positions to begin August 10, 2013. Preference will be given to qualified candidates at the Assistant or Associate Professor levels. The department has particular need for individuals with teaching and research interests in the areas of auditing, managerial, and financial accounting. However, individuals with interests in other areas will be considered. Successful candidates will have a Ph.D. in accounting from an AACSB-accredited school, a program of scholarly research consistent with the rank applied for, and instructional capabilities at both the undergraduate and graduate levels. Information about the department and its programs is available at: http://www.acis.pamplin.vt.edu. Interested candidates *must* apply online at: http://www.jobs.vt.edu (posting number 0121558) and include with the electronic application a cover letter, resume, and three letters of recommendation or names and contact information of three references. Review of applications will begin June 1, 2012. General inquiries should be directed to: Professor Greg Jenkins, Chair of the Recruiting Committee at: greg.jenkins@vt.edu, or Professor Reza Barkhi, Department Head, 3007 Pamplin Hall (0101), Blacksburg, VA 24061. Virginia Tech is an Equal Opportunity/Affirmative Action Employer.

EAST CAROLINA UNIVERSITY invites applications for a tenure-track Assistant/Associate Professor position in Accounting beginning in the 2013–2014 academic year. Applicants should be (or expect to be) terminally qualified (Ph.D. in Accounting) by August 2013, with appropriate professional certification. Our current needs place an emphasis on systems and cost. A 12 s.h. load is standard with release time granted for research and publication productivity. The normal teaching load is 9 s.h. but 6 s.h. loads are available for outstanding research productivity. Send credentials (cover letter that describes specific skills and experience relevant to this position, current resume/*vita*, current teaching evaluations, and three original letters of reference) to: Dr. Dan Schisler, Chair, East Carolina University, 3415 Bate Building, Greenville, NC 27858-4353: or via email to: schislerd@ecu.edu. Applicants must comply with the Immigration Reform and Control Act. ECU is an Equal Opportunity/Affirmative Action University and accommodates individuals with disabilities.

NEW MEXICO STATE UNIVERSITY seeks candidates for an Assistant Professor, who are required to hold or be near completion of an earned doctorate in accounting or in business administration with major in accounting from an AACSB-accredited business school. Candidates for Associate Professor are additionally required to have an established record of high-quality teaching and research, including publications in major accounting journals. The successful applicant will have responsibilities in teaching and advising, research and service to the Department, College, University, and community. The position requires continued scholarly activity, including research publications in refereed accounting journals. Candidates with teaching interests in financial and managerial accounting, accounting systems, accounting ethics, and auditing will be considered. NMSU holds business and accounting accreditation by AACSB International. The University is the state's land-grant institution and has approximately 18,000 main campus students. Preference will be given to candidates who can provide evidence demonstrating effective teaching and a solid publication record and/or potential for their level of academic experience. Submit letter of application, current resume, unofficial graduate transcripts, and list of three persons who may be contacted for references. Review of applications will begin August 20, 2012; applications received after this date may be considered. Contact: Dr. Kevin Melendrez, Box 30001/MSC 3DH, New Mexico State University, Las Cruces, NM 88003-8001; Phone: (575) 646-4901; Email: kdm@nmsu.edu.

SEATTLE UNIVERSITY invites applications for a tenure-track Assistant or Associate Professor in the Department of Accounting beginning September 2013. The Department of Accounting offers the B.A.B.A. with a concentration in Accounting and the M.P.Ac. degree, including a business valuation specialization. The Accounting Department's M.P.Ac. program is currently ranked 19th in the nation and the undergraduate program is currently ranked 21st in the nation by *U.S. News & World Reports*. The Accounting Department website can be found at: http://www.seattleu.edu/albers/inner.aspx?id=24360. Job responsibilities include teaching, research, and service. Requirements for the position include: Ph.D. in Accounting from an AACSB-accredited institution prior to the date of employment; established record or promise of excellence in scholarship and teaching; ability to teach a range of courses in the undergraduate and graduate programs in the areas of financial accounting and/or auditing. Seattle University, founded in 1891, is a Jesuit Catholic university located on 48 acres on Seattle's Capitol Hill. More than 7,700 students are enrolled in undergraduate and graduate programs within eight schools. *U.S. News & World Report*'s "Best Colleges 2012" ranks Seattle University among the top 10 universities in the West that offer a full range of master's and undergraduate programs. Applicants should submit materials online at https://jobs.seattleu.edu, including a cover letter, *curriculum vitae*, teaching and research statement, recent teaching evaluations, and a sample of research output, as well as name and contact information for three references (if available at this time). Application deadline is October 1, 2012. Seattle University is an Equal Opportunity Employer.

SALEM STATE UNIVERSITY, Bertolon School of Business at Salem State University is seeking to fill a full-time, tenure-track position in the Accounting and Finance Department for an accounting faculty member, starting Fall 2013. In addition to teaching, faculty members, as a part of a cooperative and collegial campus community, will advise students, perform college service, and pursue research. This position is advertised subject to available funding. Required qualifications include: Ph.D. or D.B.A. in Accounting (ABD considered). Preferred qualifications include: previous university/college teaching experience in accounting; experience in and commitment to teaching in a multi-racial, multi-ethnic environment with students of diverse backgrounds and learning styles; and experience in distance learning and instructional technologies. SSU is a comprehensive, publicly supported institution of higher learning located approximately 15 miles north of Boston, Massachusetts. The university enrolls more than 10,000 undergraduate and graduate students representing 27 states and 65 nations, and is one of the largest state universities in the Commonwealth of Massachusetts. Its mission is to educate and prepare a diverse community of learners to contribute responsibly to our global society. Candidates who enjoy serving as role models and mentors for a diverse student body are preferred. The salary is competitive, and commensurate with education and experience. To see the full list of benefits, review the complete job description, and apply online, please visit https://jobs.salemstate.edu/applicants/Central?quickFind=51237, and attach your resume and cover letter. Salem State University is an Equal Opportunity/Affirmative Action Employer. Persons of color, women, and persons with disabilities are strongly urged to apply.

CHRISTOPHER NEWPORT UNIVERSITY, Joseph W. Luter III School of Business invites applications for a tenure-track position in Accounting. Required qualifications include a Ph.D. or D.B.A. in Accounting. Professional certification, professional accounting experience, and experience teaching at the college level are plusses. Individuals with appropriate master's degrees who are ABD at the final stage of completion may be considered for appointment at rank of Instructor and begin the probationary appointment with the terminal degree the following year. Starting date is August 2013. The successful candidate will demonstrate the potential for excellent teaching, producing scholarly work, contributing to the intellectual life of the University, and engaging students inside and outside the classroom. Preference will be given to candidates interested in teaching managerial accounting courses, but qualified individuals in all specialty areas of accounting will be considered. Located between historic Colonial Williamsburg and the ocean resort of Virginia Beach, CNU is committed to outstanding teaching and learning, undergraduate education, and the liberal studies core. The Luter School's AACSB-accredited business curriculum attracts some of the University's best students, and requires a minimum GPA of 3.0. The business program offers students opportunities for international experiences, internships, volunteer work, and research collaboration with faculty. Full job posting (Search #8221) at: http://www.cnu.edu/equalopp/recruitment/jobopps.asp. EOE

SALEM STATE UNIVERSITY. Bertolon School of Business is seeking to fill a full-time, tenure-track position in the Accounting and Finance Department for an accounting faculty member for Fall 2013. This position is advertised subject to available funding. Required qualifications include: Ph.D. or D.B.A. in Accounting (ABD considered). Preferred qualifications include: previous university/college teaching experience in accounting; experience in and commitment to teaching in a multi-racial, multi-ethnic environment with students of diverse backgrounds and learning styles; and experience in distance learning and instructional technologies. SSU is a comprehensive, publicly supported institution of higher learning located approximately 15 miles north of Boston, Massachusetts. The university enrolls more than 10,000 undergraduate and graduate students representing 27 states and 65 nations, and is one of the largest state universities in the Commonwealth of Massachusetts. Its mission is to educate and prepare a diverse community of learners to contribute responsibly to our global society. In addition to teaching, faculty members, as a part of a cooperative and collegial campus community, will advise students, perform college service, and pursue research. Candidates who enjoy serving as role models and mentors for a diverse student body are preferred. The salary is competitive, and commensurate with education and experience. To see the full list of benefits, review the complete job description and to apply online, please visit: https://jobs.salemstate.edu/applicants/Central?quickFind=51237, and attach your resume and cover letter. Salem State University is an Equal Opportunity/Affirmative Action Employer. Persons of color, women, and persons with disabilities are strongly urged to apply.

Women, persons of color, and persons with disabilities are encouraged to apply.

KUTZTOWN UNIVERSITY, Department of Business Administration announces a tenure-track faculty position to teach Accounting, beginning in Fall 2013, subject to final budget approval. Kutztown University is located in a beautiful semi-rural area two hours from New York City and one hour from Philadelphia. Kutztown University is one of 14 universities that comprise the Pennsylvania State System of Higher Education. As part of an energetic faculty you will be teaching undergraduate accounting courses with the opportunity to teach in the M.B.A. program. Faculty are evaluated for tenure and promotion based on their contributions in three areas: (1) teaching, (2) scholarly activity, and (3) service. Ph.D. or D.B.A. in Accounting or a related area is preferred; PQ candidates considered. ABD in Accounting with expected completion within one year will also be considered. Interested applicants should respond to the address below and include the following information: (1) an up-to-date *curriculum vitae*; (2) transcripts for all academic work completed (official transcripts are required before hiring); (3) names and contact information of at least three references (letters from the referees will be required before interview); and (4) a cover letter which clearly outlines the applicant's teaching and research interests. This information should be sent to: Dr. Therese A. Maskulka, Chairperson, Accounting Faculty Search, Department of Business Administration, Kutztown University, PO Box 730, Kutztown, PA 19530. Review of applications will begin on August 27, 2012 and will continue until the position is filled.

LEHIGH UNIVERSITY seeks well-trained research scholars/teachers with strong teaching, research, communication, and interpersonal skills for one open position at the Assistant Professor rank to join its Accounting Department faculty in Fall 2013. Candidates must be able to teach financial accounting, managerial accounting, and information system courses both at the undergraduate (introductory and advanced) and graduate levels, publish related research, able to work in teams with collegial attitude, provide service, and engage in other activities commensurate with our mission. A dynamic accounting department, a world-class undergraduate accounting program, a successful M.S. in Accounting and Information Analysis program, the 31st best undergraduate business school according to Bloomberg *BusinessWeek*'s annual rankings are reasons to consider Lehigh. Applicants must submit a letter of interest, *curriculum vitae*, three letters of reference, and dissertation proposal or other scholarly work to: https://academicjobsonline.org/ajo/Lehigh/Department%20of%20Accounting. For additional information contact: Dr. Parveen P. Gupta, Chair, Department of Accounting, Lehigh University, 621 Taylor Street, Bethlehem, PA 18015; Email: ppg0@lehigh.edu; Phone: (610) 758-3443. Lehigh University is an Equal Opportunity/Affirmative Action Employer. Qualified women and minority candidates are especially encouraged to apply. Lehigh offers excellent benefits including domestic partner benefits. Visit: http://www.lehigh.edu/~inprv/faculty/worklifebalance.html

VICTORIA UNIVERSITY OF WELLINGTON, School of Accounting and Commercial Law, Wellington, New Zealand seeks to appoint a Professor of Accounting with an outstanding record of teaching and research and a record of establishing successful relationships with professional and practitioner groups. Applicants for the position must hold a Ph.D. and have strong quantitative skills to engage in and supervise research of an empirical nature. Apply at: http://www.victoria.ac.nz/sacl.

SOUTHERN ILLINOIS UNIVERSITY EDWARDSVILLE invites applications for a tenure-track position beginning in August 2013. A Ph.D. in Accounting is required, but ABDs nearing completion will be considered. Candidates should have a teaching specialization in the area of financial accounting or taxation but other specialties will be considered. Candidates must be committed to excellence in teaching and scholarly research. The Department of Accounting offers AACSB-accredited programs at both the undergraduate and master's levels. Send *vita* to: Michael L. Costigan, Chair, Department of Accounting, Southern Illinois University Edwardsville, Campus Box 1104, Edwardsville, IL 62026-1104; Email: mcostig@siue.edu. SIUE is a state university. Benefits under state-sponsored plans will not be available to holders of F1 or J1 visas. Applicants will be subject to a background check prior to an offer of employment. Southern Illinois University Edwardsville is an Equal Opportunity Employer and will not discriminate against any person on the basis of race, religion, national origin, or sex in violation of Title VII. Southern Illinois University Edwardsville prohibits discrimination against employees, applicants for employment, and students on the basis of age, color, disability, marital status, national origin, race, religion, sex, sexual orientation, or veteran's status.

STANFORD UNIVERSITY, Graduate School of Business invites applications for tenured and non-tenured faculty positions in accounting, effective September 1, 2013, from candidates at all levels and stages of their careers who are interested in financial accounting, managerial accounting, tax, and other areas. Candidates should have or expect to complete a Ph.D. by September 1, 2013, and should possess a strong and active research record. The successful candidate will be expected to conduct research and to teach both M.B.A. and Ph.D. courses in accounting. Applications should include *cv* and copies of research publications. Applicants are strongly encouraged to submit their applications electronically by visiting: http://www.gsb.stanford.edu/recruiting, and uploading their *curriculum vitae*, research papers and publications, and teaching evaluations, if applicable, to that site. Alternatively, all materials may be sent by email to: faculty_recruiter@gsb.stanford.edu, or by postal mail (non-returnable) to: Office of Faculty Recruiting, Box A, Graduate School of Business, Stanford University, 655 Knight Way, Stanford, CA 94305. However, submissions via email and postal mail can take 4–6 weeks for processing. For an application to be considered complete, all applicants must have three letters of recommendation emailed to the preceding email address, or sent via postal mail. The application deadline is December 1, 2012. Stanford University is an Equal Opportunity Employer and is committed to increasing the diversity of its faculty. It welcomes nominations of and applications from women and members of minority groups, as well as others who would bring additional dimensions of diversity to the University's research, teaching, and clinical missions.

UNIVERSITY OF HOUSTON, Department of Accountancy and Taxation, C. T. Bauer College of Business, invites applications for tenure-track appointments at all ranks for Fall 2013. Applicants for senior positions should have a national reputation for scholarship, and a record of excellence in teaching at the undergraduate and graduate levels. Applicants for junior positions must have a doctoral degree prior to appointment date and exhibit strong potential for and commitment to excellence in research and teaching. We are seeking applications in all areas of Accounting. The C. T. Bauer College of Business and the Department are AACSB-accredited. Salaries are very competitive. Application procedure: To be considered, interested applicants should submit the following documents electronically: (1) current *curriculum vitae*; (2) statement of teaching and research experience; and (3) list of 3 references with contact information to: Search Committee, Department of Accountancy & Taxation, University of Houston, C. T. Bauer College of Business, 334 Melcher Hall, Houston, Texas 77204-6021. Review of applications will begin immediately and applications will be accepted until the position is filled. SIU Carbondale is an Affirmative Action/Equal Opportunity Employer and strives to enhance its ability to develop a diverse faculty and staff and to increase its potential to serve a diverse student population. All applications are welcomed and encouraged and will receive consideration.

SOUTHEAST MISSOURI STATE UNIVERSITY is seeking applicants for Chairperson of the Department of Accounting available Fall 2013. Provide dynamic collegial leadership to a successful, progressive department with a dedicated faculty and staff. Fulfill the role and responsibilities of a chairperson as defined in the Faculty Handbook, including officially representing the department's on- and off-campus interests, evaluating faculty and staff, managing budgets, providing curricular leadership, and ensuring that the needs of students are met. Teaching in the department will be 6 credit hours per regular term. Requirements include a Ph.D. or D.B.A. in accounting, CPA, and a record of accomplishments consistent with appointment as a tenured Associate or Full Professor. Full position description available at: http://www.semo.edu/hr/employment/faculty_employment.htm. To apply, submit an electronic application via email to: facultyjobs@semo.edu. The application should include letter of interest addressing position requirements and how you learned of this position, current *curriculum vitae*, unofficial copies of transcripts, and name and current contact information for at least three references. To ensure full consideration, applications must be received by October 1, 2012.

NORTHEASTERN UNIVERSITY is seeking applications for tenure-track positions effective September 2013 at the Assistant or Associate Professor rank. Candidates must have or expect to have a doctorate in accounting or a closely related business field before the start date and be committed to excellence in research and teaching. The Accounting Group at Northeastern is nationally recognized for its high-quality behavioral accounting research focused on auditing, governance, tax, and managerial and ethical judgment and decision making. We provide a supportive environment where collaboration in research and teaching is encouraged. The position offers competitive compensation and teaching responsibilities that enable a significant level of high impact research. Rank and salary are dependent on qualifications. Summer funding, graduate assistants, and travel support are available. Accounting courses are offered at both the undergraduate and at the graduate levels (M.B.A., M.S./M.B.A., M.S.A., and M.S.Tax). For consideration, submit your cover letter, *cv*, and two samples of scholarly work to: http://www.cba.neu.edu/faculty/ and clicking on "Faculty Positions" link on the right-hand side. Northeastern University (Boston, Massachusetts) is an Affirmative Action/Equal Opportunity/Title IX Employer and welcomes applications from minorities, women, and disabled persons.

EDHEC seeks candidates who have a strong record of publication including papers in FT-ranked journals, will participate in the research work of EDHEC's Financial Analysis and Accounting Research Centre, and whose major interests are company valuation, determination of risk premium (including accounting), impact of IFRS standards on financial statements (perception of risks by account users and business management), performance management, and risk pricing. The successful candidate will also have some responsibility for teaching and course design in the academic and executive education programs of Groupe EDHEC. Contact Paul Klumpes at: paul.klumpes@edhec.edu; Phone: 00333201544530.

ILLINOIS STATE UNIVERSITY, Department of Accounting invites applications for a full-time, tenure-track Assistant or Associate Professor position in accounting. The Department of Accounting is AACSB-accredited and provides a balanced emphasis on quality teaching, research, and service. Candidates are expected to demonstrate the potential for excellence in teaching and scholarly research. Qualifications include a Ph.D. or D.B.A. in Accounting. A degree from an AACSB-accredited school is preferred. ABDs with substantial progress that are close to degree completion will be considered. Professional certification and work experience in accounting are desirable. The successful candidate will have a primary teaching interest in undergraduate and graduate courses in taxation. The normal teaching load is 9 credit hours per semester. Salary is commensurate with qualifications and experience. The selected applicant will begin August 16, 2013. To ensure full consideration, please send a formal letter of application and current *vita* to: Gerry McKean, Interim Chairperson, Illinois State University, Department of Accounting, Campus Box 5520, Normal, IL 61790-5520; Email: gerry.mckean@ilstu.edu. Illinois State is an Equal Opportunity/ Affirmative Action university and encourages diversity.

WESTERN NEW ENGLAND UNIVERSITY invites applications for a tenure-track Assistant/Associate Professor accounting position to begin August 2013. Candidates are expected to hold a doctorate in accounting or anticipate having completed all degree requirements by the starting date. The successful candidate will demonstrate a strong commitment to teaching in the undergraduate and graduate programs and to publishing scholarly research. An interest in teaching financial accounting or auditing is desirable. Western New England University is a private, independent, coeducational institution founded in 1919 and located on an attractive 215-acre suburban campus in Springfield, Massachusetts within easy access of Boston and New York City. More information about the University is available at: http://www.wne.edu. Send *vita*, teaching evaluations, research manuscript, and reference information to: Dr. Julie Siciliano, Dean, College of Business, Western New England University, 1215 Wilbraham Road, Springfield, MA 01119. Electronic submissions are encouraged and should be sent to: lori.fenton@wne.edu. Western New England University is an Equal Opportunity Employer.

IDAHO STATE UNIVERSITY, College of Business seeks a full-time tenure-track Assistant or Associate Professor or a non-tenure-track Clinical Assistant Professor in its Department of Accounting for a position available for the 2013–2014 academic year. Salary will be commensurate with experience and qualifications. Both the College of Business and the Accounting Program are accredited by AACSB. Our accounting faculty support excellent undergraduate, M.B.A., and Master of Accountancy (M.Acc.) programs. Responsibilities: The faculty member will teach at the undergraduate and graduate levels. Any emphasis area(s) except tax considered. Normal course load includes two preps and three sections per semester for AQ and four sections per semester for PQ. Peer-reviewed scholarly work, service, and research are expected of candidates for an academically qualified tenure-track position. Heavy professional experience and continuing professional involvement is expected of candidates for a professionally qualified non-tenure-track appointment. The successful candidate will demonstrate a collegial attitude, excellent communication skills, and an eagerness to support our students through a mentoring/advising process. Minimum Qualifications: Ph.D. (ABD considered if near completion) and research promise indicating an ability to conduct peer-reviewed scholarly work for a tenure-track academically qualified (AQ) position. Significant high-level accounting experience and professional certification required for a non-tenure-track professionally qualified (PQ) position. Apply URL: https://isujobs.net/applicants/jsp/shared/position/JobDetails_css.jsp?postingId=138603 Contact: Dr. Bob Picard at: picarobe@isu.edu.

DRAKE UNIVERSITY, College of Business and Public Administration, School of Accounting, invites applications for an Assistant/Associate Professor of Accounting, starting in Fall 2013, teaching primarily financial or managerial accounting at the undergraduate and graduate level. The normal teaching requirements are 9 credit hours per semester. Demonstrated effectiveness in teaching and continuing professional development is expected. A doctorate in Accounting at time of appointment is preferred, but ABD candidates close to completion will be considered. Candidates must also be able to provide evidence of demonstrated teaching effectiveness at the university-level and continuing professional development. Candidates for the Associate level must show a record of scholarly publications and an active research stream. Salary is competitive with peer AACSB institutions. Drake University is a private, comprehensive university dedicated to quality teaching. It is located in Des Moines, Iowa, with a metropolitan population over 500,000. Enrollment is selective and limited to approximately 5,500 students in the schools and colleges of the University. Both the CBPA and School of Accounting hold AACSB-accreditation. Send application letter with current *vita* listing three references to: Dr. Stephen Gara, Search Committee Chair, School of Accounting, Drake University, 2507 University Avenue, Des Moines, IA 50311: Email: Stephen.Gara@drake.edu; Website: http://www.drake.edu/hr/. Drake University is an Equal Opportunity Employer.

PORTLAND STATE UNIVERSITY seeks applicants for a full-time tenure-track position as an Assistant or Associate Professor September 16, 2013. The successful candidate will be expected to (1) publish in refereed publications, (2) develop and teach courses in taxation or financial accounting at the undergraduate and/or graduate levels, and (3) perform appropriate service activities. Salary is competitive. Qualifications: The successful candidate for this job will provide current evidence of an on-going research program and hold a doctoral degree with an emphasis in accounting from an AACSB-accredited institution or hold both a CPA and J.D. Advanced ABD candidates will be considered but must possess a doctoral degree by September 1, 2013. Preference given to applicants whose research is complementary with that of existing faculty and to those candidates with academic or professional work experience. Submit a letter of interest, *curriculum vitae*, one or two representative papers, a summary of teaching evaluations or other measures of teaching effectiveness, and contact information for three references. EEO/AA Statement: Alabama State University is an Equal Opportunity Employer and an E-Verify participant.

UNIVERSITY OF WISCONSIN–WHITEWATER, Accounting Department invites applications for multiple full-time tenure-track Assistant Professor positions in the areas of Tax, Financial, and Managerial Accounting beginning Fall 2013. Applicants should have a doctoral degree in Accounting, however, applicants with doctoral degrees in closely related fields and ABDs will be considered. The College of Business and Economics is AACSB-accredited so applicants must be academically qualified under those standards. Preference will be given to applicants with CPA certification and accounting practical experience. The UWW Accounting Department strives to be among the best regional public comprehensive university accounting departments by focusing on quality teaching, a solid research portfolio, and service. The complete position announcement is at: http://www.uww.edu/employment/unclassified.html For more information about our department go to: http://www.uww.edu/cobe/accounting/. To apply, send a letter of application, resume, contact information for three references, and evidence of teaching effectiveness. Original transcripts will be required of finalists. Application materials should be emailed to: Joanna Stradinger at: stradinj@uww.edu; or mailed to: Dr. Carol J. Normand, Search and Screen Committee Chair, Attn: Joanna Stradinger, Accounting Department, University of Wisconsin–Whitewater, 800 W. Main Street, Whitewater, WI 53190-1790. Only complete applications will be considered. Applications received by October 1, 2012 are ensured consideration. Positions will remain open until filled. UW–Whitewater is an Equal Opportunity/Affirmative Action Employer.

BOWLING GREEN STATE UNIVERSITY (BGSU) invites applicants for one tenure-track position in Accounting at the Assistant or Associate Professor rank beginning in August 2013. We are looking for one individual to support our undergraduate specializations in Accounting and Information Systems Auditing and Control, as well as our Master of Accountancy and M.B.A. programs. Preference will be given to candidates with teaching and research interests in financial accounting/reporting, auditing, and accounting information systems. Ph.D. in business with a concentration in accounting preferred. Professional experience is also highly valued. At the Assistant Professor rank, individuals who expect completion of all Ph.D. requirements by August 2013 are preferred, but the committee will consider candidates who expect to complete all degree requirements during 2013–2014. Potential or demonstrated commitment to teaching excellence, research, and service is expected with an established record being required for appointment at the Associate rank. BGSU offers a competitive salary package based upon experience and accomplishments. Applicants should send a current resume, three letters of recommendation, and a transcript from your doctoral program to: Dr. David M. Stott, Chair, Department of Accounting and MIS, Bowling Green State University, Bowling Green, OH 43403-0262. Review of applications will begin on July 15, 2012 and will continue until the positions are filled. The committee will not accept electronic or fax submissions of applications and materials. The availability of these positions is subject to final budget approval. Information on departmental programs and faculty can be reviewed at: http://www.cba.bgsu.edu/amis. BGSU is an Equal Opportunity/Affirmative Action Employer and encourages applications from women, minorities, veterans, and individuals with disabilities.

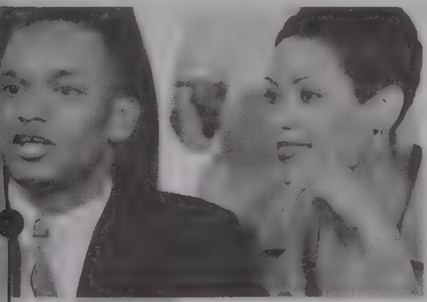
Why use ProQuest business resources from your library?

Your library and ProQuest—providing the best business information available

Whether you are a student writing a paper, an instructor recommending classroom support, an entrepreneur contemplating a new venture, or a job seeker researching regional market conditions, you'll be prepared with the resources you need—from ProQuest.

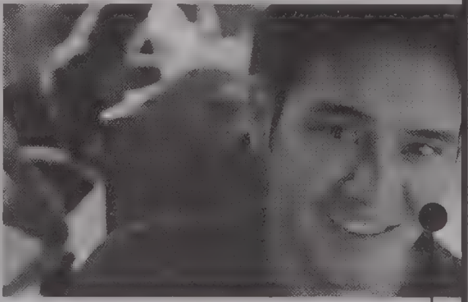
Databases like **ProQuest Accounting & Tax, ABI/INFORM** and **ProQuest Entrepreneurship** feature everything from e-books and annual reports, to education tools and market research reports. And tools like RSS feeds and email alerts keep the search going even when you're not at the computer. All of that is available from your library, via remote access, putting you on the path to discovery, anywhere, anytime.

Get free and instant access to hundreds of online databases!
Sure, you can use the open web for research, but when you're looking for authoritative and reliable content, online databases from ProQuest via your local library are your best starting point. Visit your library's website to learn more.



"While I'm in school, I'm also looking for work."

"Even from home, I can log on to get the information I need from renowned databases from ProQuest—all it takes is a library card!"



"As a small business owner, I'm always seeking resources to help guide my plans."

AMERICAN ACCOUNTING ASSOCIATION

AMERICAN ACCOUNTING ASSOCIATION

Board of Directors

President	Karen V. Pincus, University of Arkansas
President-Elect	Mary E. Barth, Stanford University
Past President	Gregory B. Waymire, Emory University
Vice President–Finance	Dale L. Flesher, The University of Mississippi
Vice President–Research and Publications	Steven J. Kachelmeier, The University of Texas at Austin
Vice President–Education	Alan Reinstein, Wayne State University
Director–Focusing on Membership	David E. Stout, Youngstown State University
Director–Focusing on International	Recep Pekdemir, Istanbul University
Director–Focusing on Professional Relations	Ken Bouyer, Ernst & Young LLP
Director–Focusing on Intellectual Property	Christine A. Botosan, The University of Utah
Director–Focusing on Segments	Anne L. Christensen, Montana State University

The Executive Director of the Association is Tracey E. Sutherland.

The American Accounting Association was founded in 1916 as the American Association of University Instructors in Accounting. Its present name was adopted in 1936. The Association is a voluntary organization of persons interested in accounting education, research, and practice.

Membership in the Association is available at the following annual rates.

Full membership:

Membership dues of $205.00 include *Accounting Education News*, and the online selection of all three Association-wide journals: *The Accounting Review*, *Accounting Horizons*, and *Issues in Accounting Education*. (This does not include Section journals.) Full members may also opt to receive *hardcopies* of AAA journals for an additional cost:

The Accounting Review	with Print Option $45.00	Total U.S. $250.00
Accounting Horizons	with Print Option $25.00	Total U.S. $230.00
Issues in Accounting Education	with Print Option $25.00	Total U.S. $230.00
All three Association-wide journals	with Print Option $95.00	Total U.S. $300.00

Associate membership:

Full-time students are eligible for associate membership. The print option is not available for Associate members.

All three Association-wide journals	U.S. $35.00

In addition, full members may belong to one or more Sections: Accounting, Behavior and Organizations; Accounting Programs Leadership Group; American Taxation Association; Auditing; Diversity; Financial Accounting and Reporting; Forensic and Investigative Accounting; Gender Issues and Worklife Balance; Government and Nonprofit; Information Systems, International Accounting; Management Accounting; Strategic and Emerging Technologies; Teaching, Learning and Curriculum; and Two-Year College. Each Section assesses its own dues, which are collected by the Association.

Editorial correspondence and revisions of manuscripts originally submitted before June 1, 2011 should be sent via email to the incoming Senior Editor, John Harry Evans III, University of Pittsburgh, at tar@katz.pitt.edu • Telephone: (412) 624-8605 • Fax: (412) 648-1693. New manuscripts must be submitted through the Manuscript Submission and Peer Review System, located at http://accr.allentrack.net. The site contains detailed instructions regarding the preparation of files for submission.

The submission fee of $200.00 for members of the AAA or $400.00 for nonmembers may be paid online (VISA or MasterCard only) at https://aaahq.org/AAAforms/journals/tarsubmit.cfm and should be paid before the article is submitted.

Requests for information concerning membership, subscriptions, dues, advertisements, and other matters related to the Association (other than submission of manuscripts) should be sent to the American Accounting Association, 5717 Bessie Drive, Sarasota, FL 34233-2399 • Telephone: (941) 921-7747 • Fax: (941) 923-4093 • Email: Info@aaahq.org. Notice of change of address should be mailed at least eight weeks in advance to ensure undelayed receipt of *The Accounting Review*.

The Accounting Review is indexed in the Social Science Citation Index, which is included in Web of Science.

The Accounting Review (ISSN 0001-4826 print and ISSN 1558-7967 online) is published six times a year in January, March, May, July, September, and November by the American Accounting Association, 5717 Bessie Drive, Sarasota, Florida 34233-2399. General subscriptions are available at the annual rates of $410 for a print copy or at $465 for a print and an electronic copy. The member subscription rate for a hard copy is $35. Electronic access is included with membership dues. Periodicals Postage Paid at Sarasota, Florida and additional mailing offices. **POSTMASTER:** Send address changes to ***The Accounting Review***, 5717 Bessie Drive, Sarasota, Florida 34233-2399.

Home Country Tax System Characteristics and Corporate Tax Avoidance: International Evidence

T. J. Atwood
Florida State University

Michael S. Drake
Brigham Young University

James N. Myers
Linda A. Myers
University of Arkansas

ABSTRACT: We examine whether three tax system characteristics—required book-tax conformity, worldwide versus territorial approach, and perceived strength of enforcement—impact corporate tax avoidance across countries after controlling for firm-specific factors previously shown to be associated with tax avoidance (i.e., performance, size, operating costs, leverage, growth, the presence of multinational operations, and industry) and for other cross-country factors (i.e., statutory corporate tax rates, earnings volatility, and institutional factors). We find that, on average, firms avoid taxes less when required book-tax conformity is higher, a worldwide approach is used, and tax enforcement is perceived to be stronger. However, the relations between tax avoidance and all three tax systems characteristics are contextual and depend on the extent to which management compensation comes from variable pay, including bonuses, stock awards, and stock options.

Keywords: *tax avoidance; tax systems; book-tax conformity; managerial incentives.*

I. INTRODUCTION

We examine the impact of three tax system characteristics—required book-tax conformity, worldwide versus territorial approach, and perceived strength of tax enforcement—on corporate tax avoidance across countries. Prior research identifies firm-specific determinants of cross-sectional variation in tax avoidance within a given country but few studies examine the impact of tax system characteristics on tax avoidance, primarily because all firms in a given country are subject to the same tax system and because changes to tax systems are infrequent.[1] We fill this void by examining tax avoidance across countries and we focus on the effects of the firm's home-country tax system characteristics.[2]

We follow Hanlon and Heitzman (2010) and define corporate tax avoidance broadly as the reduction in explicit taxes paid, and we measure tax avoidance as the difference between the firm's "unmanaged tax amount" (the home-country statutory corporate tax rate times pre-tax earnings before exceptional items) and its "managed tax amount" (current taxes paid). This difference reflects how aggressively managers pursue strategies that reduce taxes paid. As in Dyreng et al. (2008), our measure of corporate tax avoidance does not necessarily imply that firms are engaging in improper behavior since managing tax costs is a necessary and appropriate component of a firm's long-term strategy.[3] Moreover, since CEOs have incentives to both increase earnings and lower taxable income, earnings management and tax avoidance are like two sides of the same coin. Thus, in our tests, we do not distinguish earnings management from tax avoidance. Rather, we assume that managers' decisions simultaneously consider the effects of planning strategies on both book income (i.e., financial earnings) and taxable income.[4]

Our study is motivated by calls for corporate tax reform in the U.S., specifically, proposals to increase required book-tax conformity (Desai 2005; Joint Committee on Taxation [JCT] 2006; Whitaker 2006), adopt a territorial approach (Avi-Yonah 2010; Hines 2011; Hufbauer 2011), and increase enforcement actions (Shulman 2009; Department of the Treasury [DOT] 2011; Keener 2011), and by calls for more research on factors influencing tax avoidance (Shackelford and Shevlin 2001; Graham 2003; Dyreng et al. 2008; Hanlon and Heitzman 2010). Understanding the impact of tax system characteristics on corporate tax avoidance is important to governments in designing tax systems and to investors in interpreting differences in firms' corporate tax avoidance across countries.

We conduct our empirical analyses using a sample of more than 69,000 firm-year observations from 22 countries from 1995 through 2007. We regress our measure of corporate tax avoidance (*TaxAvoid*) on home-country tax system characteristics (i.e., required book-tax conformity, worldwide versus territorial approach, and perceived strength of tax enforcement) while controlling for statutory corporate tax rates as well as various country- and firm-specific variables that have been shown to influence tax avoidance in prior research. Results from our empirical analyses reveal that tax avoidance is lower, on average, for firms in home-countries with higher required book-tax conformity, a worldwide (rather than territorial) approach, and stronger perceived tax enforcement.

---

[1] See Hanlon and Heitzman (2010) for a recent review of the tax avoidance literature.

[2] We use the term "home country" to refer to the country in which the parent is incorporated. The home-country tax system plays a primary role in determining how much tax a firm pays because it dictates the final layer of tax that the firm must pay on any repatriated earnings before they can be paid out as dividends to shareholders.

[3] The terms "tax avoidance," "tax aggressiveness," "tax sheltering," "tax noncompliance," and "tax evasion" are all used in academic literature to describe various aspects of tax avoidance. We use the term "tax avoidance" to refer to all reductions of taxes paid below the "unmanaged tax amount." As such, we do not differentiate between actions that would be considered prudent tax planning versus those that would be considered abusive tax sheltering.

[4] Consistent with the idea that earnings management and tax avoidance decisions are made concurrently, Desai (2005) argues that the degradation of both financial earnings and taxable income stems from an increase in managers' ability to exploit differences between financial and tax accounting rules by structuring transactions to create advantageous book-tax differences (e.g., using derivatives, special purpose entities, etc.). Likewise, Hanlon and Heitzman (2010) assert that differences between financial earnings and taxable income are driven by a wide variety of factors and that these factors likely operate simultaneously to generate the level of book-tax differences that a firm reports.

We further investigate whether the associations between tax avoidance and tax system characteristics differ when the variable pay portion of management compensation (*VarComp*) is high (above the median) versus low (below the median). We suggest that managers have stronger incentives to increase after-tax returns (including lowering taxes) when the variable pay component of management compensation is high. Consistent with this, we find that the association between tax avoidance and required book-tax conformity is less negative when the variable portion of management compensation is high. Moreover, the negative relation between tax avoidance and the perceived strength of tax enforcement is driven by firms in countries where the variable portion of management compensation is high. Finally, the worldwide tax approach is associated with lower tax avoidance only when the variable portion of management compensation is low. These results provide evidence that the influence of tax system characteristics on tax avoidance depends on the strength of management's incentives to avoid taxes.

Overall, our results contribute to the literature that investigates cross-sectional variation in tax avoidance. We extend prior research, which generally focuses on firms within a single country, by providing evidence that cross-country differences in tax systems as well as firm-specific factors impact the extent to which firms avoid taxes. Our study should be of interest to tax policymakers concerned about declining corporate tax revenues and the increasing gap between reported earnings and taxable income since they suggest that increasing tax enforcement is likely to result in lower tax avoidance as proponents argue (Shulman 2009; DOT 2011; Gravelle 2011; Hufbauer 2011; Keener 2011; Zrust 2011). However, our results also suggest that, while proposals to require greater book-tax conformity (Desai and Dharmapala 2009) may reduce tax avoidance, incentives underlying management compensation contracts may mitigate these effects. Indeed, our results suggest that increasing book-tax conformity is unlikely to significantly reduce tax avoidance unless managers' variable compensation, as a percentage of total compensation, is also reduced.

Our results should also be of interest to investors in global markets. Prior research suggests that information about tax expense and tax disclosures in the financial statements may provide information about current and/or future earnings (Hanlon and Heitzman 2010). Understanding how tax system characteristics impact tax avoidance should help investors to better interpret the tax information contained in the financial statements when comparing firms across countries.

The remainder of this paper is organized as follows. Section II discusses prior research and develops our hypotheses, while Section III describes our research design. Section IV presents our sample selection, descriptive statistics, and test results. Section V describes robustness tests and Section VI concludes.

II. PRIOR RESEARCH AND DEVELOPMENT OF HYPOTHESES

Prior Research

Prior research documents considerable cross-sectional variation in tax avoidance and identifies firm-specific factors that explain this variation.[5] Cross-sectional differences in tax avoidance are influenced by firm-level factors such as leverage (Graham and Tucker 2006; Joulfaian 2010; Lisowsky 2010), the scale of international operations (Rego 2003; Dyreng and Lindsey 2009), and management incentives (Phillips 2003; Hanlon et al. 2007; Rego and Wilson 2008; Gaertner 2010; Robinson et al. 2010; Armstrong et al. 2012).

---

[5] Shackelford and Shevlin (2001) and Hanlon and Heitzman (2010) provide extensive reviews of prior research on tax avoidance, including studies of marginal tax rates, effective tax rates, book-tax differences, tax shelters, and uncertain tax benefits.

Prior studies primarily explore tax aggressiveness across firms within one country (and mainly within the U.S.), where all firms operate under the same tax system, financial accounting standards, and institutional factors. Although tax system characteristics likely have a strong impact on tax avoidance, these characteristics have little or no variation within countries. Thus, we examine whether three tax system characteristics—required book-tax conformity, worldwide versus territorial approach, and strength of tax enforcement—impact corporate tax avoidance across countries.

Development of Hypotheses

Our conceptual definition of tax avoidance is very broad. Specifically, we follow Hanlon and Heitzman (2010) and define tax avoidance as the reduction of explicit taxes. This definition includes tax avoidance strategies that create permanent or temporary book-tax differences as well as those that do not create any book-tax differences.[6] This definition also includes the full range of tax reduction strategies including those that are clearly legal (such as investing in tax-exempt bonds), those with uncertain tax benefits but for which minimal penalties would be assessed upon discovery by taxing authorities (such as U.S. tax return reporting positions that are undisclosed but are supported by substantial authority, or that are disclosed but have a reasonable basis), those for which more substantial penalties would be assessed but that would not be subject to criminal penalties (such as undisclosed U.S. tax return reporting positions that meet the reasonable basis standard), and those that are clearly illegal and could subject taxpayers to criminal penalties (such as abusive tax shelters and/or fraud).

We view tax system characteristics as determinants of differences in the availability of tax avoidance strategies, as well as determinants of differences in the expected costs and/or benefits of implementing tax avoidance strategies. We predict that these differences in costs and benefits will influence tax avoidance decisions even after controlling for corporate statutory tax rates and firm-specific characteristics identified in prior research.

The first tax system characteristic that we examine is the level of required book-tax conformity in the firm's home country. Firms in countries with higher required book-tax conformity have fewer opportunities to avoid taxes without decreasing reported earnings. Moreover, tax authorities act as an additional monitor of reported earnings when higher conformity between earnings and taxable income is required. Desai (2005) argues that these constraints (decreased opportunity and increased monitoring) on managers would result in less overall tax avoidance if required book-tax conformity were increased in the U.S.

Prior research suggests the amount of flexibility that firms have to report differences between taxable income and pre-tax earnings per the financial statements differs across countries (Ali and Hwang 2000; Hung 2001; Atwood et al. 2010; Lang et al. 2011). When constrained from taking tax positions that create differences between reported earnings and taxable income, managers may implement other tax-reducing strategies, such as locating more operations in tax havens or shifting more income into lower tax jurisdictions (JCT 2006). However, these alternative tax avoidance strategies are more costly to implement than strategies that create differences between reported earnings and taxable income. Thus, we conjecture that tax avoidance is more costly in countries that require more book-tax conformity than in countries that require less book-tax conformity, all else equal. For this reason, we predict a negative relation between tax avoidance and required book-tax conformity.

---

[6] For example, the decision to locate a subsidiary in a foreign country with a lower statutory tax rate and shifting income to that subsidiary may reduce explicit taxes paid without creating a difference between pre-tax earnings and the sum of the firm's taxable incomes reported in the home country and in the foreign country. That is, taxes may be avoided without creating either permanent or temporary book-tax differences in the financial statements.

Our first hypothesis is formally stated in the alternative form as follows:

> **H1:** Firms in home countries with higher required book-tax conformity engage in less tax avoidance.

The second tax system characteristic that we examine is the use of a worldwide versus territorial tax system in the home country. For parent firms located in countries with worldwide tax systems, such as the U.S., income earned by foreign subsidiaries is potentially subject to additional tax in the home country when it is repatriated via dividend payments. This additional tax is not imposed on parent firms located in countries with territorial tax systems.

Under the territorial approach, income received from foreign subsidiaries in the form of dividend payments is partially or wholly excluded from the parent firm's taxable income. For example, assume a parent in Country Y has a subsidiary in Country X. This subsidiary earns $100 in pre-tax profits, pays $20 in Country X taxes, and remits an $80 dividend to the Country Y parent. If Country Y has a territorial tax system, then the dividend from the Country X subsidiary is excluded from the parent's taxable income. Thus, the consolidated firm as a whole pays only the Country X tax on income earned in Country X.

Under the worldwide approach, dividends received from foreign subsidiaries are included in the parent firm's taxable income but foreign income taxes paid can be claimed as either a deduction or a credit (subject to limitations) to mitigate the double taxation of foreign-source income. For example, assume a U.S. parent with a 35 percent statutory corporate tax rate has a subsidiary in Country X, and the subsidiary earns $100 in pre-tax profits, pays $20 in Country X taxes, and remits an $80 dividend to the U.S. parent. The U.S. parent includes the $100 of pre-tax Country X earnings in its U.S. taxable income, which increases U.S. taxes due before credits by $35 ($100 × 0.35), but it receives a $20 foreign tax credit. Thus, the U.S. parent must remit the $15 difference between the U.S. tax and the Country X tax to the U.S. tax authorities. As a result, the after-tax income from an investment in Country X is higher for multinationals with parent firms located in countries using the territorial approach than for multinationals with parent firms located in countries using the worldwide approach.

Proponents of adopting a territorial approach in the U.S. claim that U.S. multinationals are at a competitive disadvantage, relative to multinationals in other countries, because of the additional taxes imposed in a worldwide tax system (Hines 2006; Hubbard 2006; Ousterhuis 2006). However, opponents of adopting a territorial approach in the U.S. argue that U.S. multinational firms have a number of options available to minimize or eliminate the perceived disadvantage of the worldwide tax system. For example, firms can defer paying U.S. tax by delaying payments of dividends to the U.S. parent. This deferral can be indefinite if the earnings are reinvested in the foreign country in which they are generated or invested in other foreign countries. When earnings are designated as permanently reinvested abroad, the potential future tax liability is also not recorded in the financial statements (Accounting Standard Codification Section 740). Consistent with this view, Markle (2010) finds no difference in income shifting among foreign affiliates by firms in worldwide tax systems that consistently reinvest earnings abroad versus firms in territorial tax systems. In addition, Lokken (2006) and Mandolfo (2007) argue that U.S. multinationals have refined international tax planning "to a fine art" (using deferral provisions, tax havens, hybrid entities, transfer pricing, cost-sharing arrangements, cross-crediting, etc.) so that they actually pay less in taxes than they would under a territorial approach. Fleming et al. (2008) further suggest that foreign tax credits go beyond what is required to eliminate double taxation and effectively result in a home-country subsidy on the activity that produces the foreign-source income. Thus, multinational firms in home countries with worldwide tax systems may have the ability to use international tax-planning techniques to achieve levels of tax avoidance that are at least as high as those of multinational firms resident in countries that use territorial tax systems.

Hicks et al. (2009) argue that parent firms in countries with territorial tax systems can achieve greater tax benefits from shifting income to low-tax jurisdictions because the dividends received from foreign subsidiaries are permanently exempt from tax in the home country, whereas in countries with worldwide tax systems, shifting income merely defers home-country tax. Consistent with this, Markle (2010) finds that multinational firms with home-country territorial tax regimes shift more income among their foreign affiliates overall than do firms with home-country worldwide tax regimes. This result, combined with the Hicks et al. (2009) point that tax savings from income shifting are permanent under territorial tax systems but are merely deferred under worldwide tax systems, suggests that less tax avoidance is possible for firms in home countries with worldwide tax systems. Therefore, we predict that tax avoidance will be lower among firms in home countries using a worldwide approach compared with firms in home countries using a territorial approach.

Our second hypothesis is formally stated in the alternative form as follows:

> **H2:** Firms in home countries with a worldwide approach engage in less tax avoidance than do firms in home countries with a territorial approach.

The third tax system characteristic that we examine is the perceived strength of tax enforcement. When managers perceive that government enforcement of tax rules is stronger, the higher expected probability of detection and potential for imposition of penalties may discourage tax avoidance. That is, managers may decrease tax avoidance when they believe tax authorities are more likely to detect the avoidance and impose additional taxes plus penalties.

Slemrod (2004) suggests that insights from standard deterrence models of the demand for tax avoidance—that higher penalties and higher probabilities of penalties being imposed deter tax avoidance—may not apply to corporate taxpayers because of the separation of ownership and management. Specifically, while the manager may be risk-averse, shareholders with diversified portfolios are risk-neutral. Thus, shareholders should want the manager to pursue all legal tax avoidance opportunities, including those that are very aggressive. However, there is often no clear, bright line between very aggressive tax avoidance and tax evasion. To align managers' incentives with the shareholders' interests, management compensation is tied to measures such as the effective tax rate or after-tax earnings. In this setting, enforcement efforts directed at the corporation may not deter the manager's tax avoidance decisions because the manager's contract compensates him *ex ante* for the risks of detection and, thus, may offset the deterrence effects of increased enforcement.

Chen and Chu (2005) and Crocker and Slemrod (2005) both develop formal principal-agent models of illegal corporate tax evasion when the principal (owner) is risk-neutral and the agent (manager) is risk-averse. Chen and Chu (2005) find that there is an efficiency loss due to the separation of ownership and control, while Crocker and Slemrod (2005) show that penalties imposed directly on the manager would be more effective in reducing tax evasion than penalties imposed on the corporation. Both models predict that firms evade taxes less when expected costs are higher (e.g., when the expected probability of detection and/or the penalties imposed are higher). However, a key assumption in both models is that tax evasion is illegal and management compensation contracts cannot be based on illegal actions because courts will not enforce such contracts. Thus, compensation contracts cannot be written based on the amount of tax evaded. However, these models do not address less extreme forms of tax avoidance, which may result in additional taxes paid with interest and penalties, but are not illegal. Therefore, it is not clear whether increased enforcement will deter tax avoidance overall.

Slemrod (2004) points out that the basic predictions of the deterrence model have not been subject to much empirical testing. However, two recent working papers use Internal Revenue Service (IRS) data to examine the impact of differences in the probability that a firm will be subject to a tax audit. When the probability of a tax audit is higher, Hanlon et al. (2011) find that accrual quality is higher and Hoopes et al. (2011) find that public firms take less aggressive tax positions. In addition, Desai et al. (2007) examine a sample of Russian firms following an increase in tax enforcement after the 2000 election of Vladimir Putin. They find that tax payments increased, related party trades were curtailed, and tax haven entities were abandoned. Consistent with these prior studies, we predict a negative relation between the perceived strength of tax enforcement and tax avoidance.

Our third hypothesis is formally stated in the alternative form as follows:

H3: Firms resident in countries where tax enforcement is perceived to be stronger engage in less tax avoidance.

III. RESEARCH DESIGN

Measure of Tax Avoidance

Recall that we define tax avoidance broadly as the reduction in explicit taxes paid.[7] We measure tax avoidance as the tax on pre-tax earnings computed at the home-country statutory corporate tax rate less the taxes actually paid, expressed as a percentage of pre-tax earnings.[8] We sum each element in the computation over three years.[9] Our measure of tax avoidance (*TaxAvoid*) for firm *i* in year *t* is calculated as follows:

$$TaxAvoid_{it} = \frac{\left[\sum_{t-2}^{t}(PTEBX \times \tau)_{it} - \sum_{t-2}^{t} CTP_{it}\right]}{\sum_{t-2}^{t} PTEBX_{it}} \tag{1}$$

where:

$PTEBX$ = pre-tax earnings before exceptional items (Item 21 – Item 57);[10]
τ = home-country statutory corporate income tax rate;[11] and
CTP = current taxes paid (Item 24 – the change in Item 100).[12]

---

[7] We focus on a measure of the total amount of taxes avoided, rather than on specific actions taken to avoid taxes (e.g., the strategic location of subsidiaries in foreign countries, the decision not to repatriate dividends, the amount of income shifted, investments in tax shelters, use of derivatives) because specific actions taken are differentially costly to implement and provide different benefits across countries. Moreover, specific actions taken are often unobservable in our setting.

[8] This measure is in the spirit of measuring tax avoidance using cash effective tax rates (ETRs, i.e., taxes actually paid divided by pre-tax income) for samples of U.S.-only firms (see Dyreng et al. 2008). We take the difference between taxes computed at the statutory tax rate and taxes actually paid because we draw our sample from different countries. As a result, firms from different countries face different statutory tax rates and, hence, taxes paid must be compared with "unmanaged taxes" at the home-country statutory tax rate to cross-sectionally measure the amount of taxes avoided.

[9] Dyreng et al. (2008) use one-year, five-year, and ten-year tax avoidance measures. They find that one-year measures are highly variable and are not as predictive of long-run tax avoidance as five-year or ten-year measures. Thus, we compute our tax avoidance measure over multiple years. Here, we compute a three-year measure because this time period is adequate to reduce the effects of items that reverse in just one year, but is not as limiting to our sample size as is a five-year window.

[10] Item numbers reference the Compustat Global database.

[11] We hand-collected these statutory rates from a KPMG LLP online summary, PricewaterhouseCoopers LLP's online information, and Coopers & Lybrand LLP's worldwide tax summary guides.

[12] When current tax expense (Item 24) is missing, we replace it with total tax expense less deferred taxes (Item 23 – Item 25) when available. We delete observations where current tax expense (Item 24) is missing and either total tax expense (Item 23) or deferred taxes (Item 25) is missing.

This measure of tax avoidance indicates the total amount of taxes the firm is able to avoid, relative to the tax computed at the home-country statutory corporate tax rate, regardless of whether such tax avoidance creates a book-tax difference.[13]

Tax Avoidance Model

We test for the main effects of tax system characteristics on tax avoidance (H1 through H3) with the following model, estimated using ordinary least squares (firm and year subscripts are suppressed):

$$TaxAvoid = \alpha_{year} + \alpha_{ind} + \alpha_1 BTaxC + \alpha_2 WW + \alpha_3 TaxEnf + \sum \alpha_{\kappa} Control_{\kappa} + e, \qquad (2)$$

where:

$TaxAvoid$ = tax avoidance measure from Model (1);
α_{year} = year fixed-effects;
α_{ind} = industry fixed-effects, based on the Fama-French 30 industry classification scheme;
$BTaxC$ = a measure of the level of required book-tax conformity from Atwood et al. (2010);
WW = 1 for firms in home countries with a worldwide approach, and 0 for firms in home countries with a territorial approach;
$TaxEnf$ = a measure of managers' perceptions of the strength of tax enforcement in the country, from the *1996 World Competitiveness Report*; and
$Control$ = country-level controls (consisting of the statutory corporate tax rate in the home country [*TaxRate*], the average of variable pay as a percentage of total compensation for firms in the country [*VarComp*], the cross-sectional earnings volatility [*Earnvol*], and institutional factors [*Factor*]) and firm-level controls (consisting of pre-tax return on assets [*Pre-Tax ROA*], firm size [*LogSize*], research and development expenditures [*R&D*], leverage [*Leverage*], sales growth [*SalesGrth*], and an indicator variable for multinational operations [*Multi*]).

To ensure that our results are not due to currency changes within a given country, we convert all data to U.S. dollars (using the currency translation rates available from Compustat) before computing the variables in the model.

We use the *BTaxC* measure of required book-tax conformity developed in Atwood et al. (2010).[14] This measure is based on the conditional variance of current tax expense (*CTE*) for a given level of pre-tax book income (*PTBI*) in a given country-year (i.e., $Var(CTE|PTBI)$). This measure captures the required level of book-tax conformity in the firm's home country.[15] Countries with a lower conditional variance are presumed to allow less flexibility in the reporting of taxable income for a given level of reported pre-tax earnings and, thus, have higher required book-tax conformity. To compute *BTaxC*, we use the conditional variance of current tax expense from the following model, estimated by country-year:

---

[13] Under U.S. Generally Accepted Accounting Principles (GAAP), the cash tax savings from stock options are not included in current tax expense (Hanlon and Shevlin 2002). These cash tax savings arise from the corporate tax deduction allowed when a manager exercises a nonqualified stock option. This deduction is compensation expense for tax purposes and equals the difference between the stock's fair market value on the date the stock is exercised and the price the manager paid for the stock. This tax benefit is recorded directly to equity and does not reduce income tax expense reported in the financial statement. Thus, tax avoidance by firms reporting under U.S. GAAP is likely understated by the amount of the tax savings from stock options deductions.

[14] Atwood et al. (2010) provide evidence that increasing the required level of book-tax conformity in the home country is associated with lower earnings quality, where earnings quality is measured as earnings persistence and the association between current earnings and future cash flows. They do not address whether increased required book-tax conformity is associated with more or less tax avoidance or whether firms use other mechanisms to achieve tax avoidance when required book-tax conformity is higher.

[15] Note that the *BTaxC* measure in Atwood et al. (2010) includes multinational firms. However, we find that when we eliminate all multinational firms and the foreign pre-tax income variable (*ForPTBI*) and reestimate the *BTaxC* model, the ranking of the *BTaxC* is the same. Thus, the *BTaxC* variable reflects the level of home-country book-tax conformity.

$$CTE_t = \theta_0 + \theta_1 PTBI_t + \theta_2 ForPTBI_t + \theta_3 DIV_t + e_t.$$

Here, *t* is a year indicator; *CTE* is current tax expense (Item #23 – Item #25);[16] *PTBI* is pre-tax book income (Item #21); *ForPTBI* is estimated foreign pre-tax book income (foreign tax expense (Item #51)/total tax expense (Item #23) × *PTBI*); *DIV* is total dividends (Item #34);[17] and *e* is the error term. We divide *CTE*, *PTBI*, *ForPTBI*, and *DIV* by average total assets (Item #89) to control for cross-sectional scale differences. *BTaxC* is computed as the scaled ranking of the root mean squared errors (RMSEs) from these country-year regressions. RMSEs are ranked so that countries with higher rankings in a given year have higher required book-tax conformity, i.e., we use descending ranks so that the highest RMSE in the year is ranked 0 and the lowest RMSE in the year is ranked $n-1$, where *n* is the number of included countries in that year. Firms in countries with higher *BTaxC* have less of an ability to avoid taxes using strategies that create book-tax differences in the home country. As a result, these firms may engage in less tax avoidance because tax-planning strategies that are available outside of the home country (e.g., locating operations in tax havens or shifting income to lower-tax jurisdictions) may be fewer and/or more costly to implement. Thus, H1 predicts that the association between tax avoidance and *BTaxC* will be negative ($\alpha_1 < 0$).

We use an indicator variable (*WW*) to distinguish between firms in home countries with a worldwide versus territorial approach to taxing foreign income. We hand-collected these data from *PricewaterhouseCoopers Corporate Taxes: A Worldwide Summary* guides and from the *Ernst & Young Worldwide Corporate Tax Guide* for years 1990 through 2008. These guides indicate the percentage of dividends from foreign subsidiaries that are subject to tax. In most countries, dividends are either fully taxable or fully exempt, but during our sample period, Belgium, France, Germany, and Italy exempted 95 percent of dividends from foreign subsidiaries (E&Y 2008) and in 2004, Finland adopted a system in which dividends from subsidiaries in European Union (EU) countries are tax-exempt, but dividends from subsidiaries in non-EU countries are 75 percent tax-exempt (E&Y 2004). We code countries as territorial if they exempt from tax at least 75 percent of foreign subsidiary dividends. H2 predicts that the association between tax avoidance and *WW* will be negative ($\alpha_2 < 0$).

To measure perceived tax enforcement (*TaxEnf*), we use the tax evasion index from the *1996 World Competitiveness Report*. This index is derived from a survey of more than 2,000 business executives per country. Respondents report their agreement with the statement "Tax evasion is minimal in your country" on a scale from 1 through 6 (where 1 indicates strongly disagree and 6 indicates strongly agree). Thus, higher numbers indicate that tax evasion is perceived to be lower, so the strength of tax enforcement is perceived to be higher.[18] Dyck and Zingales (2004) find a negative relation between this measure and private benefits of control (i.e., the private benefits that controlling shareholders can extract from non-controlling shareholders) across countries, suggesting that additional monitoring by tax authorities reduces these benefits. H3 predicts that the association between tax avoidance and *TaxEnf* will be negative ($\alpha_3 < 0$).

---

[16] As in Atwood et al. (2010), when total tax expense or deferred tax expense is missing, we use current tax expense, if available, otherwise we delete the observation.

[17] Dividends are included in the model to control for those countries with tax rates that depend on whether the earnings are distributed (e.g., during the transition from an imputation system to the current system in Germany). As part of our robustness tests, we estimate *BTaxC* without including dividends in the model and find that the country-year rankings are identical.

[18] We are unable to locate similar surveys in other years in order to determine whether perceptions of the strength of tax enforcement have changed over time.

We include the statutory corporate tax rate as an important control variable in determining the impact of tax system characteristics on tax avoidance. In general, the benefits of engaging in tax-planning strategies are higher when the statutory tax rate is higher, suggesting a positive relation between tax avoidance and statutory tax rates. However, prior empirical research does not provide strong evidence on the relation between statutory corporate tax rates and corporate tax avoidance. Kamdar (1997) uses time-series data from IRS audits to examine corporate tax avoidance. He finds a weak negative relation between statutory corporate tax rates and corporate tax compliance measured as the percentage of "true" income voluntarily reported, and finds no relation using four of six alternative measures. Thus, we make no specific prediction about the relation between our tax avoidance measure and statutory corporate tax rates.

We hand-collected the statutory corporate tax rates (*TaxRate*) from a KPMG LLP online summary, PricewaterhouseCoopers LLP's online information, and Coopers & Lybrand LLP's worldwide tax summary guides. These statutory corporate tax rates include both the federal income tax rate and the average effects of state, provincial, and other local government income tax rates. Since *TaxRate* is included in the calculation of *TaxAvoid*, the association between these variables may be partially mechanical. Because *TaxAvoid* includes the effects of both book-tax differences and tax-planning strategies that do not create book-tax differences (e.g., location decisions, income shifting, repatriation strategies), *TaxAvoid* can be broken down into two components. That is, $TaxAvoid = (BTD \times \tau) + (S \times (\tau - \tau^*))$, where *BTD* equals total book income less total taxable income across all jurisdictions, τ equals the statutory tax rate in the home country, *S* equals income shifted to lower tax jurisdictions, and τ^* equals the tax rate in the jurisdiction to which income is shifted. If one assumes that *BTD* and *S* are determined independently of the tax rate (i.e., $\partial\, BTD/\partial\tau = 0$ and $\partial\, S/\partial\tau = 0$), then the relation between *TaxAvoid* and τ is purely mechanical (i.e., $\partial TaxAvoid/\partial\tau = BTD + Shift$). However, if one assumes that *BTD* and *S* are functions of the home-country and foreign-country statutory tax rates (that is, $BTD = f(\tau)$, and $S = g(\tau,\tau^*)$), then $TaxAvoid = g(\tau,\tau^*) \times (\tau - \tau^*) + f(\tau) \times \tau$ and $\partial TaxAvoid/\partial\tau = (\tau - \tau^*) \times g'(\tau,\tau^*) + g(\tau,\tau^*) + \tau \times f'(\tau) + f(\tau)$. Under these assumptions, the relation between *TaxAvoid* and τ is not purely mechanical. However, because of the potential for a mechanical relation, we include the home-country statutory tax rate as a control variable.[19]

With respect to the other country-level control variables, prior research provides evidence that management incentives impact tax avoidance (Phillips 2003; Rego and Wilson 2008; Hanlon and Heitzman 2009; Gaertner 2010). Because data on individual manager salary, bonus, equity, stock options, and/or other compensation components are not available for non-U.S. firms, we use the country average of managers' variable pay as a percentage of management compensation (*VarComp*) from Towers Perrin (2005) to measure management incentives from compensation contracts.[20] This percentage is calculated as all performance-based compensation (i.e., bonuses and stock-related compensation) divided by total compensation.[21] Towers Perrin (2005) reports significant differences in the pay components of CEOs across 26 countries (22 of which are included in our sample). Specifically, average variable pay as a percentage of total compensation ranges from a high of 62 percent in the U.S. to a low of 14 percent in India. Desai and Dharmapala (2006) and Hanlon et al. (2007) suggest that incentive compensation is positively associated with tax avoidance in the U.S., so we predict that firms in countries where variable pay is a larger portion of CEO compensation will engage in more tax avoidance.

---

[19] We suggest, however, that future research should further examine the relation between statutory tax rates and tax avoidance.

[20] Towers Perrin maintains databases for compensation-planning purposes of executive compensation for both local and multinational companies in 97 countries. We believe that the broad cross-section of firms included in the Towers Perrin survey is comparable to the cross-section of firms included in our sample, and are unable to obtain similar surveys for years prior to 2005 in order to determine whether the percentage of compensation from variable pay varied for a given country over time.

[21] The understatement of tax avoidance due to the reporting of tax benefits from stock options under U.S. GAAP (see footnote 13) may induce a negative correlation between tax avoidance and the variable portion of management compensation (*VarComp*), but we note that the correlation between tax avoidance and *VarComp* is positive so this potential effect does not seem to be problematic.

Earnvol is the scaled descending decile rank of cross-sectional pre-tax earnings volatility by country-year, which controls for differences in the cross-sectional variance in pre-tax earnings. As reported in Atwood et al. (2010), *BTaxC* is positively correlated with the cross-sectional variance in pre-tax earnings. Thus, we include earnings volatility as a control in our model to ensure that the results for required book-tax conformity are not overstated due to the effects of cross-country differences in earnings volatility. We follow Atwood et al. (2010) and control for cross-country institutional factors (*Factor*) using the results of a factor analysis (untabulated) of the country's legal tradition (common law versus code law), strength of investor rights, and ownership concentration as developed by La Porta et al. (1998). We find that these variables converge to one significant factor (eigenvalue = 1.96), which explains 65 percent of the variation in the component variables. We extract this principal component (*Factor*) and include it as a control variable in our models.

Our firm-level control variables are shown in prior research to be associated with tax avoidance.[22] We control for firm profitability using pre-tax return on assets (*Pre-Tax ROA*), measured as pre-tax income before exceptional items (Item 21 – Item 57) divided by lagged total assets (Item 89). We control for firm size (*LogSize*) by taking the natural log of total assets. Our measure of intangible intensity or investment in research and development (*R&D*) is calculated as research and development expense (Item 52) divided by lagged total assets (Item 89). Leverage (*Leverage*) is calculated as total long-term liabilities (Item 108 + Item 94) divided by total assets (Item 89). Sales growth (*SalesGrth*) is the three-year average change in sales (Item 5). Finally, our multinational operations indicator (*Multi*) is set equal to 0 when foreign income taxes (Item 51) is missing or 0, and set to 1 otherwise.[23] We use an indicator variable rather than the ratio of foreign pre-tax income to total pre-tax income because Compustat Global does not provide a breakdown of domestic and foreign pre-tax income for non-U.S. multinationals. This indicator variable approach is similar to that used by Hanlon et al. (2007).[24]

Tax Avoidance Model with Incentive Compensation

We further investigate the relations between tax avoidance and tax system characteristics by allowing the coefficients to vary when the variable pay component of compensation is a higher versus lower portion of managers' total compensation. Prior research provides evidence that incentives under management compensation contracts affect tax avoidance decisions. Specifically, prior research finds that: tax avoidance is positively associated with the level of management compensation (Rego and Wilson 2008); effective tax rates are lower when managers' incentive compensation is based on after-tax versus pre-tax performance measures (Phillips 2003; Gaertner 2010); proposed IRS deficiencies are positively associated with the percentage of annual compensation that is in the form of bonuses and with the level of equity incentives from exercisable stock options (Hanlon et al. 2007); and tax avoidance is positively associated with equity risk incentives (Rego and Wilson 2011).

---

[22] See, for example, Hanlon et al. (2007), Dyreng et al. (2008), Rego and Wilson (2008), Cazier et al. (2009), Khurana and Moser (2009), Chen et al. (2010), Gaertner (2010), Hogan and Noga (2010), Lisowsky (2010), Badertscher et al. (2011), Cook and Omer (2011), and McGuire et al. (2012).

[23] We note that the Japanese companies in our sample all report missing values for foreign tax expense. We perform a search of *Mergent Online* and *Lexis Nexis Academic Universe* to identify Japanese firms with foreign subsidiaries and, in all tabulated tests, we reclassify these as multinationals. This results in the reclassification of 5,622 Japanese observations (33.8 percent of the total Japanese sample) as multinationals. We note, however, that the results for *Multi* are consistent with and without this correction.

[24] Hanlon et al. (2007) use U.S. tax return data to create an indicator variable equal to 1 if the taxpayer claimed a foreign tax credit or filed a Form 5471, whereas we base our indicator variable on the existence of a foreign income tax expense amount.

Recent models of corporate tax evasion that allow for agency costs also suggest that managerial incentives influence tax avoidance. Desai and Dharmapala (2006) show that increases in higher-powered incentives (e.g., stock option grants as a percentage of total compensation) may induce managers to engage in more or less tax-sheltering activity, and Crocker and Slemrod (2005) show that the optimal management compensation contract adjusts to offset, at least partially, the effect of sanctions against tax evasion.

These studies suggest that managers' tax avoidance decisions may be influenced by the proportion of their compensation that is comprised of bonuses, stocks, and stock options rather than fixed salaries. Moreover, the implementation of tax avoidance strategies and the receipt of any related incentive compensation generally occur several years before any related audit by taxing authorities, and even further from the payment of any additional taxes and penalties. As such, potential future audit adjustments and penalties may be less salient to managers than are the prospects for increased current incentive pay. For these reasons, we include the proportion of the manager's total compensation that is in the form of variable pay (i.e., bonus, stock, and stock options) in our tax avoidance model and allow the coefficients on the tax characteristic variables to differ when variable compensation as a percent of total compensation is high versus low. We test for the influence of variable compensation using the following model:

$$\begin{aligned} TaxAvoid = {} & \beta_{year} + \beta_{ind} + \beta_1 BTaxC \times High + \beta_2 BTaxC \times Low + \beta_3 WW \times High \\ & + \beta_4 WW \times Low + \beta_5 TaxEnf \times High + \beta_6 TaxEnf \times Low + \beta_7 TaxRate \times High \\ & + \beta_8 TaxRate \times Low + \sum \alpha_\kappa Control_\kappa + e \end{aligned} \tag{3}$$

where:

High = 1 if *VarComp* is above the median (0 otherwise);
Low = 1 if *VarComp* is below the median (0 otherwise); and
All other variables are as previously defined.

We expect that the coefficients will differ across the *High* and *Low* categories, but make no prediction about the signs of these differences.

Tax Avoidance Model with Accruals Components

We further investigate the relations between tax avoidance and tax system characteristics after controlling for accruals components. We do this to determine whether our tax system characteristics impact tax avoidance accomplished through accruals management alone or whether they also impact tax avoidance accomplished through other tax-planning strategies. Our approach is similar in spirit to that in Desai and Dharmapala (2006) who attempt to isolate the portion of tax aggressiveness that is attributable to tax sheltering as opposed to accruals management.

In our models, we allow the coefficients on the accruals components to vary based on the reliability classifications developed in Richardson et al. (2005). This allows us to investigate whether tax avoidance is more closely associated with certain types of accruals. Richardson et al. (2005) measure total accruals (*ACC*) as the sum of the change in net non-cash working capital (ΔWC), the change in net noncurrent operating assets (ΔNCO), and the change in net financial assets (ΔFIN), so $ACC = \Delta WC + \Delta NCO + \Delta FIN$. Here, Δ is the change operator, *WC* is current operating assets (Item 75 – Item 60) minus current operating liabilities (Item 104 – Item 94), *NCO* is noncurrent operating assets (Item 89 – Item 75 – Item 80 – Item 81) minus noncurrent operating liabilities (Item 118 – Item 104 – Item 106), and *FIN* is financial assets (Item 62 + Item 80 + Item 81) minus financial liabilities (Item 106 + Item 94 + Item 199). We add the separate accruals measures to the tax avoidance models above. The augmented models (with firm and year subscripts suppressed) are as follow:

$$TaxAvoid = \alpha_{year} + \alpha_{ind} + \alpha_1 BTaxC + \alpha_2 WW + \alpha_3 TaxEnf + \alpha_4 \Delta WC + \alpha_5 \Delta NCO + \alpha_6 \Delta FIN + \sum \alpha_\kappa Control_\kappa + e \quad (4)$$

$$TaxAvoid = \beta_{year} + \beta_{ind} + \beta_1 BTaxC \times High + \beta_2 BTaxC \times Low + \beta_3 WW \times High + \beta_4 WW \times Low + \beta_5 TaxEnf \times High + \beta_6 TaxEnf \times Low + \beta_7 TaxRate \times High + \beta_8 TaxRate \times Low + \beta_9 \Delta WC + \beta_{10} \Delta NCO + \beta_{11} \Delta FIN + \sum \alpha_\kappa \mathrm{Control}_\kappa + \mathrm{e} \quad (5)$$

All variables are as previously defined.

We expect a positive relation between *TaxAvoid* and accruals because prior research indicates that accruals are positively related to tax sheltering (Wilson 2009; Lisowsky 2010), but we allow this relation to vary with the reliability of the accruals. With the accruals variables included in the model, we interpret our results for *BTaxC*, *WW*, and *TaxEnf* as their impact on non-accrual-related tax avoidance.

IV. SAMPLE SELECTION, DESCRIPTIVE STATISTICS, AND TEST RESULTS

We select our sample from all firm-year observations in the Compustat Global Industrial/Commercial database from 1993 through 2007 with sufficient data to calculate the variables in Models (1) through (5).[25] We apply several data filters. First, we limit our sample to the 33 countries included in Atwood et al. (2010) because these are the countries for which we can estimate required book-tax conformity. Second, we limit our sample to the 22 countries included in Towers Perrin (2005) because these are the countries for which we can estimate CEO variable pay. Third, we require three years of positive pre-tax earnings before exceptional items (*PTEBX*) for our calculations of tax aggressiveness. Thus, for all of our observations, $\sum_{t-2}^{t}(PTEBX \times \tau)_{it}$ will be greater than zero. Fourth, we delete all firm-year observations from countries that do not have at least 20 firms with available data in the year.[26] This sample selection procedure yields 69,301 firm-year observations from 22 countries.[27] Table 1 presents a list of the countries in our sample, their corresponding sample periods, and the number of total observations per country[28] as well as the country medians for each of the variables in Models (2) and (3).

Table 1 reveals considerable variation in the number of observations per country, ranging from 323 observations from India to 18,454 observations from the U.S. Thus, in a sensitivity test we also examine whether sample concentration influences our results by calculating the median for each variable by country-industry-year and entering the resulting median value into Models (2) and (3).

---

[25] Our sample period is as in Atwood et al. (2010) since we use their methodology to estimate book-tax conformity.

[26] Atwood et al. (2010) require 40 usable observations per country-year. Given that we have greater time-series data requirements, we relax this restriction to 20 usable observations.

[27] To remove the influence of potential outliers, we winsorize all continuous variables at the top and bottom 1 percent for each year.

[28] The earliest year reported in Table 1 is 1995 because we require three years of data to construct our tax aggressiveness variables.

This procedure results in a sample of 6,119 country-industry-year observations. While this procedure reduces the influence that any particular country has on the results, it also removes much of the variation in the dependent variable (*TaxAvoid*) and in the firm-specific control variables (*Pre-TaxROA*, *LogSize*, *R&D*, *Leverage*, *SalesGrth*, and *Multi*). Thus, we draw our main inferences from the results that use the full sample, and view the results that use the country-industry-year medians sample as a very conservative robustness test.

Table 2, Panel A provides descriptive statistics for the full sample. The median level of *TaxAvoid* is 7.9 percent of pre-tax earnings. Dyreng et al. (2008) report median annual cash effective tax rates of 25.6 percent. This would imply a median level of tax avoidance of about 9.4 percent of pre-tax earnings (i.e., the 35 percent statutory corporate tax rate less the 25.6 percent cash effective tax rate). Thus, the median *TaxAvoid* for our sample of multinational firms is lower than that for the sample of U.S. firms in Dyreng et al. (2008). However, Table 1 indicates that the median *TaxAvoid* for U.S. firms in our sample is 9.5 percent, so our median tax avoidance measure for U.S. firms is consistent with the median reported by Dyreng et al. (2008). We also note that 73.7 percent of our sample observations are from countries with a worldwide tax approach, and 30.2 percent of our sample observations have multinational operations.

Panels B and C of Table 2 provide Pearson (above the diagonal) and Spearman (below the diagonal) correlations among the variables. All reported correlations are statistically significant at the 5 percent level or better with the exception of the correlations in bold. For both the Pearson and Spearman correlations, *BTaxC*, *WW*, and *TaxEnf* are negatively correlated with our tax avoidance variable, while *VarComp* is positively correlated with tax avoidance. Our tax enforcement variable (*TaxEnf*) is very highly correlated (Pearson Rho = 0.63) with our control variable for institutional factors (*Factor*). Following Gleason and Lee (2003), we conduct a test of collinearity (untabulated) by regressing the dependent variable (*TaxAvoid*) on all of the independent variables and calculating the variance inflation factors (VIFs) for each variable. We find that the average VIF is 2.5 and the highest VIF across the three regressions is 7.5, which is well below the generally accepted threshold of 10. This suggests that multicollinearity is not a problem in our model.

We now turn to the main tests of our hypotheses. We estimate all regressions models using ordinary least squares regression and we assess statistical significance using standard errors adjusted for firm clustering of residuals when using the full sample and for industry clustering of residuals when using the medians sample.[29]

Table 3 presents the results from estimating Model (2). Columns A and B present the results from estimating Model (2) using the full sample and the country-industry-year medians, respectively. Consistent with H1, tax avoidance is negatively associated with *BTaxC* in both samples, indicating that firms engage in less tax avoidance on average when their home countries have higher required book-tax conformity. An increase from the 25th percentile to the 75th percentile of required book-tax conformity results in a 23.74 percent decrease in *TaxAvoid* for the full sample (and a 35.76 percent decrease for the country-year medians sample).[30] These results suggest that firms in home countries with greater required book-tax conformity engage in significantly less tax avoidance.

---

[29] For regressions estimated using the medians sample, we do not adjust for firm clustering of residuals because individual firm-year observations do not appear in this country-industry-year sample.

[30] We calculate the percent increase in tax avoidance from moving from the 25th percentile to the 75th percentile as follows: [0.706 (*BTaxC* at Q3 per Table 2, Panel A) – 0.152 (*BTaxC* at Q1 per Table 2, Panel A)] × –0.036 (the coefficient on *BTaxC* per Table 3, Column A) ÷ 0.084 (mean *TaxAvoid* per Table 2, Panel A) = 23.67 percent. We perform similar calculations for our variables of interest below, but we do not provide the details of each calculation for parsimony.

TABLE 2

Our measure of tax aggressiveness (*TaxAvoid*) for firm *i* in year *t* is calculated as follows:

$$TaxAvoid_{it} = \frac{\left[\sum_{t-2}^{t}(PTEBX \times \tau)_{it} - \sum_{t-2}^{t} CTP_{it}\right]}{\sum_{t-2}^{t} PTEBX_{it}} \tag{1}$$

PTEBX = pre-tax earnings before exceptional items (Item 21 − Item 57);
τ = statutory tax rate;
CTP = current taxes paid (Item 24 − the change in Item 100);
BTaxC = proxy for the level of required book-tax conformity, following Atwood et al. (2010);
WW = 1 for firms in countries with worldwide tax systems, and 0 for firms in countries with territorial tax systems;
TaxEnf = proxy for the level of tax enforcement in the country, from the 1996 *World Competitiveness Report*;
TaxRate = statutory tax rate;
VarComp = average of variable pay as a percentage of total compensation for firms in the country, from the Towers Perrin *Worldwide Total Remuneration Report, 2005–2006*;
Factor = control for cross-country institutional factors using the results of a factor analysis of the country's legal tradition (common law versus code law), strength of investor rights, and ownership concentration as developed by La Porta et al. (1998);
Earnvol = country-level control variable for earnings volatility;
Pre-TaxROA = pre-tax return on assets;
LogSize = log of assets;
R&D = research and development expenditures;
Leverage = leverage;
SalesGrth = sales growth;
Multi = indicator variable for multinational operations;

(continued on next page)

TABLE 2 (continued)

Δ = change operator;
WC = current operating assets (Item 75 − Item 60) minus current operating liabilities (Item 104 − Item 94);
NCO = noncurrent operating assets (Item 89 − Item 75 − Item 80 − Item 81) minus noncurrent operating liabilities (Item 118 − Item 104 − Item 106);
FIN = financial assets (Item 62 + Item 80 + Item 81) minus financial liabilities (Item 106 + Item 94 + Item 199);
CommonLaw = 1 if the country's legal tradition is common-law, 0 if code-law;
InvRights = the investors' rights score developed by La Porta et al. (1998); and
OwnCon = the ownership concentration variable developed by La Porta et al. (1998).

All reported correlations in Panels B and C are statistically significant at the 5 percent level or better with the exception of the correlations in bold. Pearson correlations are reported above the diagonal and Spearman correlations are reported below the diagonal.
All variables are as defined in Table 2, Panel A.

Consistent with H2, we find that firms in home countries with a worldwide approach engage in less tax avoidance than do firms in home countries with a territorial approach for both the full and medians sample. Using the full sample, the results suggest that firms in home countries with a worldwide approach avoid taxes by 13.10 percent less than do firms in home countries with a territorial approach (and 12.66 percent less using the median sample). Contrary to suggestions in Lokken (2006), Mandolfo (2007), and Fleming et al. (2008), we find no evidence that firms resident in countries with worldwide tax systems use sophisticated international tax-planning techniques to produce results that are better (i.e., that avoid more taxes) on average than those produced by firms resident in countries with territorial tax systems. Rather, our results suggest that on average, the worldwide approach results in less tax avoidance than does the territorial approach. Our results are consistent with those of Markle (2010), who finds that multinational firms subject to the worldwide approach engage in less tax-motivated income shifting than do multinational firms subject to the territorial approach. The results suggest that this reduced income shifting contributes to lower tax avoidance by multinational firms subject to the worldwide approach.

Consistent with H3, we find that tax avoidance is negatively associated with managers' perceptions of the strength of tax enforcement (*TaxEnf*). When perceived tax enforcement increases from the 25th percentile to the 75th percentile, tax avoidance decreases by 18.88 percent of the average for the full sample (and 16.22 percent for the medians sample). This overall result is consistent with the standard deterrence model of tax evasion—that higher penalties and higher probabilities of penalties being imposed deter evasion—and with the empirical results in Desai et al. (2007), Hanlon et al. (2011), and Hoopes et al. (2011).

We also find that tax avoidance is positively associated with the statutory corporate tax rate (*TaxRate*). When the statutory corporate tax rate increases from the 25th percentile (31 percent) to the 75th percentile (40.7 percent), tax avoidance increases by 6.58 percent of the average for the full sample (and 6.26 percent for the medians sample). However, we interpret this result with caution due to the potential for a mechanical relation between our tax avoidance measure and statutory tax rates (as previously discussed).

Consistent with prior research, we also find that manager incentives (*VarComp*) are positively associated with tax avoidance. Specifically, when the variable component of management compensation increases from the 25th percentile (22.0 percent) to the 75th percentile (62.0 percent), tax avoidance increases by 68.57 percent of the average for the full sample (and 66.33 percent for the medians sample). We further explore this effect below by allowing the associations between the tax system characteristics and tax avoidance to vary across firms where *VarComp* is above versus below the median.

With respect to the remaining country-level control variables in Model (2), we first find that tax avoidance is lower when the level of cross-sectional pre-tax earnings volatility within a country

In all regressions, we assess statistical significance using standard errors adjusted for firm clustering for the full sample (Column A) and industry clustering for the medians sample (Column B). We use one-tailed tests when a sign is predicted.

All variables are as defined in Table 2, Panel A.

(*Earnvol*) is higher. As discussed in Atwood et al. (2010), *BTaxC* is highly positively correlated with cross-sectional pre-tax earnings volatility.[31] By including *Earnvol* in our regression, we ensure that our *BTaxC* results are not driven by differences in the cross-sectional volatility of pre-tax earnings rather than required book-tax conformity. Next, we find that cross-country institutional factors (*Factor*) are also negatively associated with tax avoidance, suggesting that tax avoidance is lower in common law countries with stronger investor rights and lower ownership concentration. Including this variable ensures that our tax system characteristics results are not due solely to their correlation with this set of institutional features across countries.

With respect to firm-level control variables, we find that tax avoidance is higher for firms with higher pre-tax return on assets (*Pre-Tax ROA*). Consistent with prior research (Rego 2003; Cazier et al. 2009; Wilson 2009), this result indicates that more profitable firms, which have the greatest incentive to reduce taxes, engage in more tax avoidance. We also find that tax avoidance is lower for large firms (*LogSize*), consistent with Rego (2003), who finds that, for a broad sample of U.S. firms, worldwide effective tax rates (ETRs) increase with firm size. These results are consistent with larger firms engaging in less tax avoidance, as well as with prior literature suggesting that larger firms may act to reduce potential political costs (Zimmerman 1983; Omer et al. 1993).[32] Contrary to prior research that finds a positive relation between R&D expenditures and tax avoidance (Dyreng et al. 2008) and between R&D expenditures and uncertain tax benefits (Cazier et al. 2009), we find no association between tax avoidance and research and development (*R&D*) in our models. However, consistent with prior research that finds a positive association between tax avoidance and leverage (Dyreng et al. 2008) and between uncertain tax benefits and leverage (Cazier et al. 2009), we find that tax avoidance is increasing in leverage (*Leverage*).[33] We also find that firms with higher *SalesGrth* engage in more tax avoidance, consistent with Badertscher et al. (2011) who find that sales growth is negatively associated with annual cash ETRs, suggesting that firms with higher sales growth engage in more tax avoidance.[34] Finally, we find less tax avoidance in firms with multinational operations (*Multi*). Prior research provides mixed evidence on the relation between multinational operations and tax avoidance. Rego (2003) finds that the more extensive a multinational's foreign operations, the higher its ETR, suggesting lower tax avoidance, but Wilson (2009) finds that firms with foreign income are more likely to be tax-shelter participants and Cazier et al. (2009) find that U.S. firms with more extensive foreign operations have greater uncertain tax benefits. Our results are more consistent with those in Rego (2003), suggesting that multinationals engage in less tax avoidance overall than do solely domestic firms.[35]

---

[31] In our sample, the Pearson correlation is 0.75 (see Table 2, Panel B).

The Effect of Variable Compensation on the Relations between Tax Avoidance and Tax System Characteristics

Table 4 explores the relations between tax avoidance and tax system characteristics by allowing these relations to vary for firms in countries with high versus low variable compensation (i.e., *VarComp* above and below the median). Columns A and B present the results from estimating Model (3) for the full and medians samples, respectively. Our focus is on the tests of coefficient equality presented at the bottom of the table.

With respect to the relation between tax avoidance and book-tax conformity, the tests of coefficient equality reveal that, for both the full and medians samples, the association between tax avoidance and required book-tax conformity is significantly less negative for firms in countries where the proportion of compensation that is variable (*VarComp*) is high. In fact, when using the full sample, the relation is positive for firms with high *VarComp*. When using the medians sample,

---

[32] Note, however, that prior research provides mixed evidence on the relation between firm size and tax avoidance. Contrary to findings in Rego (2003), Cazier et al. (2009) find that larger firms report greater uncertain tax benefits under FIN 48 and Wilson (2009) finds that they are more likely to be tax-shelter participants, consistent with the argument that larger firms engage in more complex tax avoidance transactions.

[33] Note, however, that findings in prior research do not suggest a clear relation between leverage and tax avoidance. In contrast with findings in Dyreng et al. (2008) and Cazier et al. (2009), leverage is negatively associated with tax sheltering (Graham and Tucker 2006; Wilson 2009) and with corporate tax evasion (Joulfaian 2010).

[34] Note, however, that Cazier et al. (2009) find that sales growth is negatively associated with uncertain tax benefits, suggesting that firms with higher sales growth engage in less tax avoidance.

[35] We note that Wilson (2009) uses a sample of 59 firms accused of tax-shelter participation and Cazier et al. (2009) use a sample 578 firm-years that first reported uncertain tax benefits under FIN 48 in 2007. Both are small sample studies where observations are drawn from a population of firms that are considered to be tax aggressive by definition. On the other hand, the sample used in Rego (2003) includes a broad cross-section of U.S. firms (5,379 firm-years). Similarly, our sample includes a broad cross-section of firms from 22 countries. We suggest that this is likely why our results are more consistent with Rego (2003).

*, **, *** Indicate significance at 10, 5, and 1 percent, respectively.

In all regressions, we assess statistical significance using standard errors adjusted for firm clustering for the full sample (Column A) and industry clustering for the medians sample (Column B). We use one-tailed tests when a sign is predicted.

All variables are as defined in Table 2, Panel A.

the relation is still negative but it is significantly less negative for firms in home countries with high variable compensation. Thus, book-tax conformity has less of an influence on managers' tax avoidance decisions when managers' compensation contracts provide them with greater incentives to avoid taxes. This result is consistent with results in Hanlon et al. (2007) and Rego and Wilson (2011), which examine tax deficiencies and effective tax rates among U.S. firms. Our results suggest that bonus and equity compensation arrangements motivate managers to undertake more risky tax-planning strategies when countries allow less flexibility in reporting differences between earnings and taxable income.

The tests of coefficient equality reveal that, for the full sample, the negative association between tax avoidance and the use of a worldwide approach is driven by firms in countries with low variable compensation. In addition, for firms in countries where *VarComp* is above the median, the tax approach in the home country (worldwide versus territorial) has no effect on tax avoidance. Note, however, that when we use the medians sample, we find no evidence of a relation between tax avoidance and the tax approach regardless of the level of variable compensation. Overall, these results provide some evidence of a relation between a worldwide approach and tax avoidance, but we refrain from drawing strong inferences given the medians sample results.

With respect to the relation between tax avoidance and the perceived strength of tax enforcement, tests of coefficient equality reveal that tax avoidance is decreasing in the strength of tax enforcement only when the variable portion of compensation is high. This result holds for both the full and the medians samples. A possible explanation for this result is that managers in countries with low variable pay are not motivated to engage in tax avoidance activities even when the strength of enforcement is lower and, as a result, stronger enforcement has no effect.

Finally, tests of coefficient equality indicate that tax avoidance is increasing in the statutory corporate tax rate only when the variable portion of compensation is high. In fact, when *VarComp* is below the median, the relation between tax avoidance and the statutory corporate tax rate is not significant in the full sample and is negative in the medians sample. This result suggests that tax avoidance is increasing in the statutory tax rate only when management compensation is strongly tied to reported earnings, as is bonus and equity compensation. Overall, the results from our medians tests confirm that the variable pay portion of management compensation impacts the relation between tax avoidance and tax system characteristics because managers are incentivized to engage in more tax avoidance when tax avoidance leads to higher compensation.

The Effects of Accruals Components

We now analyze the relations between accruals components and tax avoidance. Table 5, Panel A, Columns A and B present the results of Model (4) for the full and medians samples, respectively. Here, we find that all three accruals components are positively associated with tax avoidance, indicating that some tax avoidance is achieved through accruals management. However, the results for the tax systems characteristics are essentially the same as in Model (2). The only exception is that the relation between tax avoidance and *TaxRate* is no longer significant for the medians sample.

Table 5, Panel B, Columns C and D present the results of Model (5) for the full and medians samples, respectively. Again, all three accruals components are positively associated with tax avoidance and the results for the tax systems characteristics are essentially the same as in Model (3). Thus, the relations between tax avoidance and the tax systems characteristics are not driven solely by tax avoidance through accruals management. This result suggests that altering home-country tax system characteristics not only impacts managers' tax avoidance through accruals management, but also tax avoidance through other mechanisms such as the use of tax havens, transfer pricing, cost sharing arrangements, tax shelters, etc.

TaxRate × HighVarComp = TaxRate × LowVarComp				146.40***			52.94***

*, **, *** Indicate significance at 10, 5, and 1 percent, respectively.
In all regressions, we assess statistical significance using standard errors adjusted for firm clustering for the full sample (Columns A and C) and industry clustering for the medians sample (Columns B and D). We use one-tailed tests when a sign is predicted.
All variables are as defined in Table 2, Panel A.

In sum, we provide evidence that three tax system characteristics—required book-tax conformity, worldwide versus territorial approach, and the perceived strength of tax enforcement—impact tax avoidance after controlling for the statutory corporate tax rate and for firm-specific factors identified in prior studies. Moreover, the degree to which tax system characteristics impact tax avoidance depends on the structure of management compensation contracts—specifically the extent to which management compensation comes from variable pay. We suggest that this occurs because bonus and equity compensation provides greater incentives for managers to avoid taxes regardless of the tax system characteristics in the home country.

V. ROBUSTNESS TESTS

In this section, we report the results of a number of untabulated robustness tests of our main model estimated with the full sample. First, we re-estimate our tax avoidance variable using pre-tax earnings *unadjusted* for exceptional items in order to investigate whether the results are influenced by our decision to use pre-tax earnings *before* these exceptional items. We find that all results for our tax systems characteristics are robust.[36]

Second, to test whether associations between tax avoidance and the tax system characteristics are driven solely by multinational firms, we remove all firms with multinational operations (where $Multi = 1$) and estimate our models without the *Multi* variable. We find that the results for *BTaxC* and *TaxEnf* are robust, but the coefficient for *WW* is not significant at conventional levels. However, when we estimate the model with only the multinational firms in the sample, we find that the results for *WW* and *TaxEnf* are robust, but the coefficient on *BTaxC* becomes positive and significant, indicating that the negative relation between tax avoidance and *BTaxC* is driven by domestic-only firms. This suggests that firms without foreign operations have available fewer tax avoidance strategies that do not create book-tax differences and, thus, higher required book-tax conformity is a more effective deterrent to tax avoidance for firms with only domestic operations.

Prior studies examining cross-country differences in the properties of accounting earnings use an indicator variable approach to measure book-tax conformity (e.g., Ali and Hwang 2000; Hung 2001; Leuz et al. 2003) where the indicator variable is based on subjective assessments of each country's book-tax conformity level.[37] Therefore, as a robustness test, we replace our *BTaxC* variable with the indicator variable used in those studies and find that all of our inferences about the effects of book-tax conformity and the remaining tax system characteristics hold.

Finally, we consider the impact of firms reporting under International Financial Reporting Standards (IFRS) versus domestic accounting standards. We find that the results for all three of our tax system characteristics hold when we add an indicator variable for firm-years reported under IFRS to both Models (2) and (4).

VI. CONCLUSIONS

This study examines whether tax system characteristics (i.e., required book-tax conformity, worldwide versus territorial approach, and perceived strength of tax enforcement) impact tax avoidance. We find that firms avoid more taxes, on average, when the home country has lower required book-tax conformity, a worldwide approach, and a lower perceived strength of tax enforcement. Moreover, the extent to which tax avoidance is associated with these tax system characteristics depends on the portion of management compensation that is from variable pay (i.e., bonuses, stocks, and stock options).

Our paper responds to proposals for tax reform in the U.S. and to calls for more research on the determinants of tax avoidance. Our results suggest that, in addition to firm-specific factors identified in prior research (i.e., performance, size, intangibles, debt financing, growth, and the presence of multinational operations), tax avoidance is driven by home-country tax system characteristics and the interaction between those characteristics and the structure of management compensation contracts.

---

[36] For all of our additional tests, we define results as "robust" when inferences drawn from coefficient sign and statistical significance (using $p < 0.10$ or better) are the same as those drawn from coefficients reported in the main tables. We discuss all results that are not robust in the text.

[37] Hung (2001) constructs the book-tax conformity variable using five factors derived from international tax and accounting summaries: the existence of deferred taxes; whether additional accelerated depreciation is allowed; whether amortization periods depend on tax laws; whether lease capitalization depends on tax laws; and a subjective determination of the relation between book and tax income. These factors may be suggestive, but many other factors result in differences between accounting earnings and taxable income in countries with low required book-tax conformity, and their measure is very highly correlated with an indicator variable for common versus code law countries.

Our paper has implications for tax policymakers in evaluating proposed tax reforms. First, our results provide evidence that supports proposals to decrease tax avoidance in the U.S. by increasing the strength of enforcement efforts. Second, proposals to increase required book-tax conformity may deter tax avoidance for domestic-only firms, but are likely to be less effective for multinational firms that have more opportunities to avoid taxes using strategies that do not create book-tax differences in the home country. Third, if the U.S. adopted a territorial approach, then tax avoidance is likely to increase, rather than decrease. Finally, the structure of management compensation contracts (specifically, the proportion of compensation that is variable) significantly impacts managers' tax avoidance responses to tax system characteristics.

We suggest two caveats regarding our results. First, using an indicator variable for the worldwide versus territorial tax system is a very simple test of differences across these two systems and we view our results as a first step in understanding the impact of this tax system characteristic on tax avoidance. We suggest that further research is needed in this area. Second, there is the potential for a mechanical relation between our tax avoidance measure and the statutory tax rate. Thus, we include the statutory tax rate as an important control variable, but we suggest this is an important area that should be addressed by future research.

Audit Quality and the Trade-Off between Accretive Stock Repurchases and Accrual-Based Earnings Management

ABSTRACT: We examine whether audit quality affects the trade-off between accrual-based and real earnings management. We hypothesize that firms motivated to manage earnings per share (EPS) to meet or beat consensus analysts' forecasts are more likely to engage in accretive stock repurchases (a form of real earnings management) when their ability to manage earnings through accruals is constrained by high audit quality. We find that firms with high audit quality are more likely to use accretive stock repurchases and less likely to use accrual-based earnings management to meet or beat consensus analysts' forecasts. Our results are robust to various controls for endogeneity concerns.

Keywords: *real earnings management; stock repurchases; audit quality; audit industry specialization.*

I. INTRODUCTION

We examine whether audit quality affects managers' choices between accrual-based earnings management and accretive stock repurchases,[1] one form of real earnings management. We focus on accretive stock repurchases where managers' motivations

[1] Stock repurchases affect both the numerator and denominator of reported EPS. Opportunity costs (in terms of forgone potential profit) associated with the cash used to fund stock repurchases affect the numerator and the timing and amount of stock repurchases affect the number of shares in the denominator. Stock repurchases are defined as accretive when the numerator and denominator effects of a repurchase jointly increase reported EPS by at least $0.01.

are to meet or beat earnings per share (EPS) targets rather than to execute normal financing activities. While prior research provides evidence that high audit quality is negatively associated with managers' ability to opportunistically report accruals (Krishnan 2003; Balsam et al. 2003), our paper examines whether managers constrained in their use of accrual-based earnings management are more likely to use open-market stock repurchases as a substitute. Similar to accrual-based earnings management, open-market stock repurchases affect EPS, involve managerial discretion, and lack adequate disclosure prior to their execution. However, unlike accrual-based earnings management, stock repurchases are not subject to auditor scrutiny since they involve decisions about a real financing activity. Given the difference in auditor scrutiny, we argue that in the presence of high audit quality, managers trade off the use of accrual-based earnings management and are more likely to use accretive stock repurchases to meet or beat consensus analysts' EPS forecasts.

Our study brings together and extends two research streams. First, Hribar et al. (2006) examines open-market stock repurchases and provides evidence that firms use accretive stock repurchases to meet or beat analysts' forecasts. We extend their paper by examining whether accretive stock repurchases are more frequently used when accrual-based earnings management is likely constrained by the presence of high audit quality. Second, prior research (Cohen and Zarowin 2010; Chi et al. 2011; Zang 2012) examines the trade-off between operational real earnings management activities (i.e., cash flow from operations, production costs, and discretionary expenses) and accrual-based earnings management for firms employing high-quality auditors. Evidence from these studies is mixed. These studies document a trade-off for seasoned equity offering (SEO) firms (Cohen and Zarowin 2010) and for firms sharing strong incentives to manage earnings upward (Chi et al. 2011), while Zang (2012) fails to document a trade-off around earnings benchmarks. We extend these studies by presenting evidence of a trade-off using a financing activity, open-market stock repurchases, as the form of real earnings management focused on meeting or beating analysts' forecasts. Examining accretive stock repurchases is advantageous because they are not subject to potential misspecifications present in measures of operational real earnings management that rely on fitted models (Cohen et al. 2011). In addition, our use of both industry auditor specialization and propensity score matching addresses concerns raised by Lawrence et al. (2011) that other firm characteristics, such as client size, subsume Big N as an appropriate measure of audit quality.

We examine firms that meet or beat consensus analysts' forecasts *ex post* to determine whether firms employing industry-specialist auditors (Hogan and Jeter 1999; Krishnan 2003; Gul et al. 2009) are more likely to use repurchases to meet or beat analysts' forecasts as compared to other firms who are able to do so absent an accretive stock repurchase. We similarly test whether firms with industry-specialist auditors are less likely to use discretionary current accruals to meet or beat analysts' forecasts as compared to firms that are able to do so absent the use of discretionary current accruals. We also directly compare firms that likely share a common *ex ante* expectation of missing consensus analysts' forecasts, but *ex post* meet or beat consensus analysts' forecasts either through accretive stock repurchases or discretionary current accruals. Our findings provide consistent evidence that firms that both engage industry-specialist auditors and meet or beat analysts' forecasts are more likely to use accretive stock repurchases and less likely to use discretionary current accruals to meet or beat analysts' forecasts *ex post*.

Our contribution of documenting a trade-off between real earnings management and accrual-based earnings management to meet or beat consensus analysts' forecasts not only extends prior accounting research, but also has implications in corporate governance. As boards of directors and investors rely on high audit quality to curtail accrual-based earnings management, they should be aware that managers may substitute accretive stock repurchases to meet or beat EPS forecasts. If a higher frequency of stock repurchases motivated by earnings management incentives potentially obfuscates earnings quality or harms long-term firm value, then alternative governance mechanisms may be necessary to curtail this behavior. We discuss these implications in the conclusion of the paper.

In addition to our main tests, we perform several additional tests to address potential concerns with our results. We provide evidence that our results are robust when we explicitly control for expected repurchases in our models, alleviating concerns that analysts and investors fully anticipate share repurchases. Additionally, we examine whether our results are driven by observable differences in firm characteristics and/or misspecification in regression analysis. Our results remain robust when we use propensity score matching on auditor industry specialization to more directly control for firm characteristics that could spuriously drive our main results. We also provide evidence that earnings management incentives around analysts' forecasts are an important component of our findings. Finally, our results are robust for the first three quarters of the fiscal year, which indicates that results in the fourth quarter, when auditor oversight is more stringent, do not drive our main results.

The remainder of the paper is as follows. Section II discusses the prior literature and develops our hypotheses. Sections III and IV present the research methodology and the results of the paper, respectively. Section V reports the sensitivity analyses. Section VI discusses the implications of our findings and concludes the paper.

II. PRIOR LITERATURE AND HYPOTHESES

Earnings Benchmarks and Stock Repurchases

Analyst forecasted EPS is commonly used as a performance benchmark in capital markets. Firms that consistently meet or beat analysts' EPS forecasts enjoy higher credibility (Graham et al. 2005) and valuation premiums (Kasznik and McNichols 2002; Brown and Caylor 2005) that persist even if EPS is knowingly managed (Bartov et al. 2002). When EPS benchmarks are missed, firms suffer severe stock price losses (Skinner and Sloan 2002), managerial compensation declines (Matsunaga and Park 2001), and managers perceive that their reputations are at risk (Graham et al. 2005).

Managers engaging in earnings management select from two broad categories of mechanisms. Accrual-based earnings management occurs when managers choose purposefully to influence earnings through accounting choices and estimates (Healy and Wahlen 1999). Real earnings management involves managerial decisions affecting both cash flows and reported earnings, such as R&D expenditures, capital investment decisions, and stock repurchases. Real earnings management is a departure from normal business activities that focuses more on short-term reporting goals than on promoting firm value (Roychowdhury 2006). Both methods of earnings management are questionable because they are actions managers take to mislead stakeholders about firm performance or influence accounting-based contractual arrangements (Healy and Wahlen 1999).[2]

Bartov (1993) and DeFond and Jiambalvo (1994) find that managers use accruals when faced with the prospect of just missing analysts' forecasted EPS. Payne and Robb (2000) show that managers use accruals to manipulate EPS to meet or beat analysts' forecasts when forecast dispersion is low and Burgstahler and Eames (2006) document that managers meet or beat EPS forecasts through both accrual-based earnings management and expectations management. In addition, Ayers et al. (2006) find that efforts to meet EPS targets through accruals extend to pseudo targets that may, in part, relate to analysts' forecasts. Barton and Simko (2002) suggest that aggressive accrual-based earnings management is constrained by the cumulative nature of accruals, suggesting that managers may turn to other earnings management tools when those limits are reached. In contrast, Beaver et al. (2007) argues that the asymmetric nature of income taxes and special items may drive the distribution of earnings near earnings benchmarks rather than earnings management incentives. Consistent with this finding, Dechow et al. (2003) find that small-profit-and-loss firms have similar proportions of both total and positive discretionary accruals and fail to document an association between accrual-based earnings management and meeting or beating analysts' forecasts. Overall, prior research provides general, but not unqualified support for managers' use of accrual-based earnings management to meet or beat earnings benchmarks.

---

[2] Managerial choices between accrual-based and real earnings management is not assumed to be an "either/or" decision. Instead, we expect that in the face of higher audit quality, managers may still misreport accruals, but at a reduced rate. In lieu of this, managers may increase their use of real earnings management techniques.

A few studies examine real earnings management to meet or beat EPS targets. Roychowdhury (2006) finds a positive association between real earnings management and meeting or beating analysts' forecasted EPS. With respect to accretive stock repurchases as a real earnings management tool, Hribar et al. (2006) find that accretive stock repurchases occur more frequently when firms are faced with an EPS shortfall and show that negative stock price responses are tempered in the presence of accretive stock repurchases. In addition, Bens et al. (2003) find that firms pressured to demonstrate EPS growth are more likely to use stock repurchases when faced with the dilutive effects of employee stock options. Our paper extends the literature related to real earnings management focused on meeting or beating an EPS benchmark and investigates whether audit quality affects the use of accretive stock repurchases as a real earnings management tool.

Earnings Management and Audit Quality

Audit quality is the joint probability that an auditor will discover and report material misstatements found in financial statements (DeAngelo 1981). Auditor industry specialization as a proxy for audit quality has been widely studied in the literature. Bedard and Biggs (1991) find that as auditors' industry-specific expertise increases, their ability to locate data errors also increases. Industry-specific auditors more likely identify extraordinary transactions, have more exposure to industry best practices, and have improved ability to identify inherent and control risks (Krishnan 2003). The use of industry-specialist auditors is found to be negatively correlated with violations of accounting standards (O'Keefe et al. 1994) and restatements (Romanus et al. 2008), and positively associated with disclosure quality (Dunn and Mayhew 2004). Together, these studies document a link between high audit quality and the presence of industry-specialist auditors.

Prior research (Krishnan 2003; Balsam et al. 2003) also provides evidence that firms engaging high-quality auditors are associated with constrained accrual-based earnings management. These studies document that clients of industry specialists have lower discretionary accruals than clients of non-industry specialists, consistent with industry specialists constraining opportunistic accrual choices.[3] These studies suggest the presence of high audit quality potentially constrains the attempted use of accruals-based earnings management because of the higher risk that the behavior will be discovered.

In contrast, auditors do not scrutinize real earnings management since their responsibility is to provide reasonable assurance that financial statements are presented in accordance with generally accepted accounting principles. Auditors ensure that the financial statements faithfully represent the real activities of firms, but are not required to evaluate managers' motivations for decisions related to real activities. Although Roychowdhury (2006) asserts that real earnings management potentially imposes greater long-term costs on firms because it has a negative effect on future cash flows, he also argues that accrual-based earnings management imposes significantly greater short-term costs on managers. This makes real earnings management an attractive choice for managers who are motivated to achieve short-term earnings goals, but are inhibited by high audit quality and therefore limited in their ability to use accrual-based earnings management techniques.

---

[3] Balsam et al. (2003) and Krishnan (2003) use the absolute value of discretionary total accruals. We model "as-if" earnings by subtracting discretionary current accruals from reported net income. We posit that discretionary current accruals better reflect managerial efforts to manage short-term earnings benchmarks such as quarterly analysts' forecasts.

Evidence relating audit quality to a trade-off between the use of accrual-based and real earnings management is mixed. Cohen and Zarowin (2010) provide evidence that firms with Big N auditors are more likely to engage in real earnings management than accrual-based earnings management when involved in a seasoned equity offering. Chi et al. (2011) find that auditor specialization, and to a lesser extent, Big N auditors, are positively associated with real earnings management and negatively associated with accrual-based earnings management in a combined sample of firms that have strong incentives to manage earnings in order to meet or just beat earnings benchmarks or to support seasoned equity offerings. Conversely, using earnings benchmarks, Zang (2012) fails to document a positive association between Big N auditors and real earnings management.

Cohen et al. (2011) examine the estimation models used to construct proxies for real earnings management and raise concerns that the models are likely to be misspecified. They suggest matching on performance as a partial solution, but note that this approach is also subject to specification concerns. Our use of stock repurchases circumvents these issues because they do not involve estimation models and therefore are less subject to misspecification. Additionally, Lawrence et al. (2011) suggest that the effect of Big N auditors may reflect fundamental differences in client characteristics rather than differential audit quality. We address this concern by using industry-specialist auditors as our proxy for high audit quality and also use propensity score matching as an additional test to ensure that our results are not driven by differences between firms with and without industry-specialist auditors.

Accretive Stock Repurchases as a Real Earnings Management Tool

Stock repurchases with the potential to increase reported EPS typically take the form of open-market repurchases, which occur when firms buy shares of their own stock on the open market (Vermaelen 2005). The transaction for open-market repurchases involves an actual stock buyback and corresponding cash expenditure. Open-market repurchases accounted for 94.3 percent of all repurchases and 95.2 percent of the total dollar value of shares repurchased during the 1990s (Grullon and Ikenberry 2000). Open-market repurchase programs must be formally approved by a firm's board of directors, typically target 5 percent of its total share base, last two to three years, and on average result in the repurchase of 77 percent of the targeted number of shares initially approved (Stephens and Weisbach 1998). Our tests focus on open-market repurchases.

The net effect of stock repurchases on EPS depends jointly on three factors: (1) the timing of the repurchase, (2) the number of shares repurchased, and (3) the forgone future returns from the cash used to repurchase stock.[4] The first two factors increase EPS by decreasing the EPS denominator. Stock repurchases that are larger and occur earlier in a quarter have a greater influence on the denominator of reported EPS because of their stronger effect on the time-weighted average of shares outstanding. The third factor decreases EPS by decreasing the EPS numerator because of forgone returns that the cash used in the repurchase could have generated. Repurchases are accretive only when the timing and amount are sufficient to outweigh the decretive impact of the forgone returns.

---

[4] The following discussion assumes that EPS is positive and that the numerator and denominator effects of a repurchase increase reported EPS by at least \$0.01. In our sample selection, we eliminate firm-quarters reporting non-positive EPS and round EPS amounts to the nearest \$0.01.

Similar to other real earnings management activities, stock repurchases are likely to be costly to firms because the cash used in the repurchase is not available for other income-generating activities. Firms that have more profitable uses of cash are less likely to engage in repurchases as an EPS management tool. As a result, managers must consider the trade-offs between using accretive stock repurchases and other earnings management activities.

Although boards of directors approve open-market repurchase programs, managers are left with considerable discretion with respect to the timing of a stock repurchase (Vermaelen 2005; Cook et al. 2003). In addition, the Securities and Exchange Commission (SEC) requires limited disclosure about repurchases by public firms. Adopted in 1982, SEC Rule 10b-18 originally required firms to disclose amounts spent on stock repurchases. The rule was amended in December 2003 to provide additional disclosures about the average price per share, the number of shares repurchased as part of a repurchase program, and the maximum number of shares that may be repurchased in the future under a repurchase program.

The SEC disclosure requirements are limited to reporting required in quarterly financial reports filed after the quarter end. Therefore, analysts and investors are unlikely to be able to precisely anticipate current-quarter repurchase effects on EPS. The combination of managerial flexibility and limited mandatory disclosures enables firms to use open-market stock repurchases as an effective real earnings management device.

Hypotheses

We focus our study on two hypotheses incorporating accretive stock repurchases, accrual-based earnings management, and audit quality. We argue that high audit quality is likely to constrain the use of discretionary accruals to meet or beat analysts' forecasts and, therefore, firms with high audit quality are more likely to use accretive stock repurchases as a substitute. While H1 focuses on the general association between audit quality and accretive stock repurchases, H2 examines the association between audit quality and the potential trade-off between accretive stock repurchases and accruals-based earnings management. Both are formally stated as null hypotheses as follows:

H1: High audit quality *is unrelated* to the use of accretive stock repurchases to meet or beat consensus analysts' forecasts.

H2: High audit quality *is unrelated* to a trade-off between the use of accretive stock repurchases and accrual-based earnings management to meet or beat consensus analysts' forecasts.

III. METHODOLOGY

Identification of Firms Suspected of Using Accretive Stock Repurchases for Real Earnings Management

Firms repurchase common stock for multiple reasons,[5] so it is important that our research design identifies firms that likely use accretive stock repurchases to manage EPS. Therefore, we identify firms that would have missed their quarterly consensus analysts' forecasts, but actually meet or beat forecasts because they made an accretive stock repurchase. We term these suspect repurchases.

---

[5] Skinner (2008) provides examples of competing motivations, including the signaling of future prospects, the issuing of stock options, and using stock swaps as part of merger and acquisition activities. These competing motivations may result in accretive repurchases, but we distinguish them from efforts to manage EPS.

Since firms do not formally disclose the exact timing of stock repurchases in their financial reports, we must estimate the effects of stock repurchases on reported EPS. We follow Hribar et al. (2006) in estimating the weighted average common shares outstanding absent a stock repurchase. We estimate the EPS denominator as the beginning common shares outstanding plus 50 percent times the number of shares issued during the quarter.[6] This procedure assumes that shares are issued evenly over the quarter and allows the repurchase timing parameter to vary across firm-quarters. If a firm does not employ a stock repurchase for a particular period, we set common shares outstanding equal to the number of common shares reported outstanding at the end of that period.

Alternative uses for the cash used to repurchase stock (i.e., growth opportunities and debt refinancing) affect the numerator of EPS and can greatly influence managers' decisions to use repurchases as an EPS management tool (Hribar et al. 2006). Therefore, we follow Hribar et al. (2006) in estimating opportunity costs associated with stock repurchases by calculating the forgone dollar return on cash used for repurchases (C_t). We estimate excess cash as cash balances in excess of 6 percent of assets for retail firms and 2 percent of assets for all other firms (Copeland et al. 2000). If excess cash is greater than or equal to the repurchase dollar amount, then we calculate the forgone return by multiplying the repurchase dollar amount by the three-month Treasury bill rate for the quarter. If excess cash is less than the repurchase dollar amount, we assume the firm borrows cash in order to execute the repurchase. In such cases, we apply a firm's average interest rate to the incremental funds borrowed.[7] We convert the estimated forgone dollar return into an after-tax amount using Graham and Mills' (2008) simulated marginal tax rates, which are highly correlated with marginal rates based on actual tax returns.[8]

We calculate both the actual and pre-repurchase forecast error to identify suspect repurchases where firm-quarters meet or beat consensus analysts' forecasts, but would have missed the forecasts absent accretive stock repurchases. Actual forecast error (*ACTUAL_FE*) is reported EPS minus the final consensus analysts' forecasts for each firm-quarter. Consistent with Hribar et al. (2006) and Roychowdhury (2006), we assume that managerial expectations at the beginning of a quarter are represented by the final actual consensus forecasts for the quarter.

To construct the pre-repurchase forecast error, we first compute EPS "as if" firms did not repurchase stock during a quarter. We calculate *ASIF_EPS1* by estimating the denominator and numerator effects of accretive stock repurchases on EPS as follows:

$$ASIF\_EPS1_{i,t} = \frac{NI_{i,t} + C_{i,t}}{SHARESOUT_{i,t-1} + 0.5{*}SHARESISSUED_{i,t}}.$$

---

[6] Prior to December 17, 2003, SEC Rule 10b-18 did not require firms to disclose the number of shares issued or the number of shares repurchased as part of a repurchase program. Therefore, it is necessary to estimate the number of shares issued and repurchased for a significant number of observations that occur prior to Rule 10b-18. As necessary, we follow Stephens and Weisbach (1998) to estimate the number of shares repurchased by dividing the dollar amount of common stock repurchased by the average monthly closing stock price for the quarter. We then calculate the number of shares issued as ending shares outstanding minus beginning shares outstanding plus shares repurchased. To address concerns over estimation error, we apply the estimation procedure to firm-quarters where actual repurchases are available and find that the two are highly correlated (> 0.95, p-value < 0.0001). We use actual repurchases when available, but this additional test reduces concerns over estimation error when actual repurchases are unavailable. Our results remain robust when using the estimation method used by Hribar et al. (2006).

[7] We estimate each firm's borrowing rate following Francis et al. (2005). We calculate a firm's borrowing rate by taking interest expense divided by average debt for the quarter. If the information is not available to estimate a firm's borrowing rate, then we use the average industry (two-digit SIC) borrowing rate for that quarter.

[8] We thank John Graham for providing data on marginal tax rates.

In this calculation, $ASIF\_EPS1_{i,t}$ represents the estimated EPS absent accretive stock repurchases. $NI_{i,t}$ is reported earnings before extraordinary items available to common shareholders for the firm-quarter. $C_{i,t}$ is the estimated forgone dollar return on cash used for accretive stock repurchases. $SHARESOUT_{i,t-1}$ is the reported number of diluted common shares outstanding if analysts' forecast diluted EPS, otherwise primary common shares outstanding, at the beginning of the firm-quarter. Finally, $SHARESISSUED_{i,t}$ is the actual or estimated number of common stock shares issued during a firm-quarter depending on data availability. All variable descriptions are provided in Appendix A.

Next, we remove the EPS effect of stock repurchases from the actual forecast error. We label the EPS effect of stock repurchases as *EPSImpact1* and calculate it as follows:

$$EPSImpact1_{i,t} = ReportedEPS_{i,t} - ASIF\_EPS1_{i,t}.$$

EPSImpact1 is positive for accretive stock repurchases and negative for decretive stock repurchases.

The pre-repurchase forecast error is calculated as the actual forecast error less the EPS effect of share repurchases. Specifically:

$$ASIF\_FE1_{i,t} = ACTUAL\_FE_{i,t} - EPSImpact1_{i,t}.$$

ASIF_FE1 is negative for firm-quarters that would have missed consensus analysts' forecasts absent the effects of accretive stock repurchases. For firms that do not repurchase common stock, *ASIF_FE1* equals *ACTUAL_FE*.

Finally, we define suspect repurchases as those that would have missed analysts' forecasts by five cents or less, but are able to meet or beat forecasts by no more than five cents with a stock repurchase. Specifically, we construct an indicator variable ($SUSPECT\_REPURCHASE1_{i,t} = 1$) as our measure for suspect repurchases, where *ASIF_FE1* is $\geq -\$0.05$, but $< \$0.00$ *and ACTUAL_FE* is $\geq \$0.00$, but $\leq \$0.05$ for a firm-quarter.[9] *SUSPECT_REPURCHASE1* is equal to 0 for all other firm-quarters. Consistent with prior research (Dhaliwal et al. 2004; Cook et al. 2008; Gleason and Mills 2008), we limit the construction of *SUSPECT_REPURCHASE1* to within five cents of analysts' forecasts to reduce the influence of motivations for stock repurchases unrelated to efforts to manage EPS within our setting.

Our final identification of suspect repurchases is based on (1) *ex ante* managerial expectations of falling short of consensus analysts' forecasts and (2) *ex post* use of accretive stock repurchases by managers used specifically to meet or beat consensus analysts' forecasts of EPS. As *ex ante* expectations of falling short or *ex post* reported EPS deviates further from analysts' forecasts, repurchases that increase EPS are likely less motivated by or are a noisier measure of earnings management behavior. Since real earnings management in the form of accretive stock repurchases expends significant amounts of firm resources, it can be a very costly form of earnings management. Therefore, accretive repurchases are most likely to occur as an EPS-management tool as negative values of *ASIF_FE1* approach 0, making it more likely they are helpful in meeting or beating analysts' forecasts. Similarly, as *ACTUAL_FE* becomes increasingly positive, repurchase behavior is less likely to be an effort to manage EPS to meet analysts' forecasts.

---

[9] This definition of suspect repurchases captures 85 percent of repurchase firm-quarters with *ex ante* managerial expectations of falling short of analysts' forecasts and *ex post* use of accretive repurchases to meet or beat analysts' forecasts. Our main results are robust when we expand the definition to 95 percent of possible suspect repurchases. As expected, our results become less robust as we further increase the forecast error limits.

Identification of Firms Suspected of Using Accrual-Based Earnings Management

We similarly identify firm-quarters during which firms appear to be using accrual-based earnings management to meet or beat analysts' forecasts and term these suspect accruals. We identify suspect accrual firms as those that would have missed analysts' forecasts absent the use of discretionary current accruals by five cents or less, but were able to meet or beat the forecasts by no more than five cents with their use. Our tests employ discretionary current accruals (see Guenther 1994; Teoh et al. 1998) because earnings management efforts focused on small changes in EPS and one-time quarterly benchmarks are more likely to be focused on current operating accruals.

Following Louis (2004), we measure quarterly discretionary current accruals using a two-step approach. First, we model normal current accruals within each two-digit SIC industry year as a function of both the change in revenue and the change in receivables for each firm-quarter using the following equation:

$$\frac{Current\ Accruals_{i,t}}{ATQ_{i,t-1}} = \beta_1\left(\frac{1}{ATQ_{i,t-1}}\right) + \beta_2\left(\frac{\Delta REVQ_{i,t} - \Delta RECQ_{i,t}}{ATQ_{i,t-1}}\right) + \varepsilon_{i,t}.$$

Current accruals are measured as the difference between quarterly income before extraordinary items and quarterly operating cash flows less depreciation and amortization expense. The change in revenue and change in receivables is the difference between the current and prior quarter of each measure, respectively. The residual from the model, $\varepsilon_{i,t}$, represents discretionary current accruals and is equal to actual current accruals less estimated current accruals. The model scales discretionary current accruals by lagged total assets ($ATQ_{i,t-1}$) so we multiply the regression residual by its corresponding lagged total assets to calculate an unscaled measure of discretionary current accruals ($DACC_{i,t}$).

Similar to our approach for constructing suspect repurchases, we calculate "as-if" EPS absent discretionary current accruals (net of income taxes) as follows:

$$ASIF\_EPS\_ACCRUALS_{i,t} = \frac{NI_{i,t} - DACC_{i,t}(1 - T_{i,t})}{Weighted\ Average\ SHARESOUT_{i,t}}.$$

$NI_{i,t}$ is income before extraordinary items available to common shareholders, $DACC_{i,t}$ is as defined above, and $T_{i,t}$ is the firm's estimated marginal tax rate. The numerator provides an estimate for net income absent the effects of discretionary current accruals. *Weighted Average SHARESOUT*$_{i,t}$ is the shares used by the firm to calculate EPS, and is diluted shares when analysts' forecast diluted EPS, and primary shares otherwise. Next, we isolate the impact of discretionary current accruals on EPS (*EPSImpact1_ACCRUALS*) as follows:

$$EPSImpact1\_ACCRUALS_{i,t} = ReportedEPS_{i,t} - ASIF\_EPS\_ACCRUALS_{i,t}.$$

EPSImpact1_ACCRUALS is positive for income-increasing discretionary current accruals and negative for income-decreasing discretionary current accruals.

We use the actual forecast error (*ACTUAL_FE*) and "as-if" forecast error absent discretionary current accruals (*ASIF_FE_ACCRUALS*) to identify suspect current accruals. Actual forecast error (*ACTUAL_FE*) is calculated as before and the "as-if" forecast error absent discretionary accruals is calculated as the actual forecast error less the EPS impact from discretionary current accruals. Specifically:

$$ASIF\_FE\_ACCRUALS_{i,t} = ACTUAL\_FE_{i,t} - EPSImpact1\_ACCRUALS_{i,t}.$$

ASIF_FE_ACCRUALS is negative for firm-quarters that would have missed consensus analysts' forecasts absent the effects of discretionary current accruals.

Finally, we define suspect accruals as those that would have missed analysts' forecasts by five cents or less, but are able to meet or beat forecasts by no more than five cents with discretionary current accruals. We construct an indicator variable ($SUSPECT\_ACCRUALS_{i,t} = 1$) as our measure for suspect accruals, where $ASIF\_FE\_ACCRUALS \geq -\$0.05$, but $< \$0.00$ *and* $ACTUAL\_FE$ is $\geq \$0.00$, but $\leq \$0.05$ for a firm-quarter. *SUSPECT_ACCRUALS* is equal to 0 for all other firm-quarters.

Audit Quality

We use an industry-specialist auditor designation as our measure of high audit quality. Consistent with prior research (e.g., Hogan and Jeter 1999; Krishnan 2003; Gul et al. 2009), we define industry specialization as the Big N audit firm with the largest market share (in terms of clients' total assets[10]) within each two-digit SIC industry group on an annual basis.[11] High audit quality is equal to 1 ($HAQ_{i,t} = 1$) when the audit firm is classified as an industry-specialist auditor, and 0 otherwise.

Empirical Models

Our empirical model for suspect repurchases uses the following logistic regression:

$$\begin{aligned} SUSPECT\_REPURCHASE1_{i,t} = {} & \alpha + \beta_1 HAQ_{i,t} + \beta_2 Repurchase_{i,t-1} + \beta_3 Repurchase_{i,t-2} \\ & + \beta_4 Forecast\ Dispersion_{i,t} + \beta_5 Cash_{i,t-1} + \beta_6 CAPEX_{i,t-4,t-1} \\ & + \beta_7 Dividend\ Yield_{i,t-1} + \beta_8 Debt_{i,t-1} + \beta_9 Size_{i,t-1} \\ & + \beta_{10} Size^2_{i,t-1} + \beta_{11} Size^3_{i,t-1} + \beta_{12} ROA_{i,t} + \beta_{13} MTB_{i,t} \\ & + e_{i,t}. \end{aligned} \tag{1}$$

Suspect repurchases ($SUSPECT\_REPURCHASE1_{i,t} = 1$) are modeled as a function of high audit quality as well as a firm's prior stock repurchases, cash levels, capital expenditures, dividends, debt levels, size, performance, and growth. We use nonlinear firm size terms consistent with Gul et al. (2009). We also include *Forecast Dispersion*, calculated as the standard deviation of the individual analyst' forecasts for each firm-quarter, as a control for the predictability of a firm's EPS and the definitiveness of the firm's EPS target in a quarter (Payne and Robb 2000).

$\beta_1(HAQ_{i,t} = 1)$ captures the relation between high audit quality and the likelihood that accretive stock repurchases are used to manage EPS. A positive and significant estimate for β_1 is consistent with a positive association between high audit quality and EPS management through accretive stock repurchases.

---

[10] Some past studies use audit fees within industry to define "expert," but fee data are only available after the year 2000. We use the total assets measure since both measures are used in the literature and our sample predates 2000. As a sensitivity test, we do not require the industry expert be a Big N auditor. The results of our tests are qualitatively similar using this alternative measure.

[11] Alternatively, Reichelt and Wang (2010) provide evidence that audit quality is systematically associated with joint national and city-specific auditor industry expertise. They use two definitions of industry specialist. The first definition requires an audit firm to have the largest market share of audit fees in an industry (two-digit SIC) by at least 10 percent. The second definition requires an audit firm to have a significant market share in an industry (30 percent of the market for national expertise and 50 percent of the market for city-specific expertise). Our results are qualitatively similar based on the second definition, but are not robust based on the first definition.

Our empirical model for suspect accruals uses the following logistic regression:

$$\begin{aligned} SUSPECT\_ACCRUALS_{i,t} = {} & \alpha + \beta_1 HAQ_{i,t} + \beta_2 Forecast\ Dispersion_{i,t} + \beta_3 Cash_{i,t-1} \\ & + \beta_4 CAPEX_{i,t-4,t-1} + \beta_5 Dividend\ Yield_{i,t-1} + \beta_6 Debt_{i,t-1} \\ & + \beta_7 Size_{i,t-1} + \beta_8 Size^2_{i,t-1} + \beta_9 Size^3_{i,t-1} + \beta_{10} ROA_{i,t} + \beta_{11} MTB_{i,t} \\ & + e_{i,t}. \end{aligned} \tag{2}$$

Suspect accruals ($SUSPECT\_ACCRUALS_{i,t} = 1$) are modeled similar to suspect repurchases, except that we exclude prior stock repurchases as control variables. Once again, $\beta_1(HAQ_{i,t} = 1)$ captures the relation between high audit quality and the likelihood that discretionary accruals are used to manage EPS. A negative and significant estimate for β_1 is consistent with a negative association between high audit quality and EPS management through discretionary accruals.

Sample Selection

We derive our sample from quarterly financial statement data obtained from the Compustat Xpressfeed North America database for the 22-year period from 1988 to 2009. Our analysis is limited to the post-SFAS 95 period since we require information from cash flow statements to identify stock repurchases and to estimate discretionary accruals. We use lagged data to estimate our models, which limits our sample period to 1989–2009. We eliminate financial institutions, transportation companies, and utilities because regulatory restrictions are likely to constrain their ability to repurchase stock (Bens et al. 2003). In addition, quarterly EPS forecast data must be available in the unadjusted consensus International Brokers' Estimate System (I/B/E/S) file. We require at least two analysts' forecasts for each firm-quarter to construct our forecast dispersion measure. We also eliminate firm-quarters reporting non-positive EPS since accretive stock repurchases do not increase EPS for firms reporting zero income or losses. Finally, we remove firm-quarters with repurchases that are more than 20 percent of common shares outstanding. These are unlikely to be open-market repurchases (Hribar et al. 2006) or repurchases associated with EPS management.

We further refine the sample to more directly address H1 and H2. For our first two main tests, we individually compare suspect repurchases and suspect accrual firm-quarters to firm-quarters that are able to meet or beat consensus analysts' forecasts absent an accretive stock repurchase or discretionary accruals. Therefore, we limit observations to firm-quarters where $SUSPECT\_REPURCHASE1_{i,t} = 1$, $SUSPECT\_ACCRUALS_{i,t} = 1$, or $ACTUAL\_FE$ is $\geq$ \$0.00, $\leq$ \$0.05 absent stock repurchases or discretionary accruals. This reduces the sample to 23,290 observations, of which 1,894 are suspect repurchase firm-quarters and 3,232 are suspect accrual firm-quarters.

Our third test directly compares suspect repurchase to suspect accrual firm-quarters. This analysis includes only firm-quarters where $SUSPECT\_REPURCHASE1_{i,t} = 1$ or $SUSPECT\_ACCRUALS_{i,t} = 1$. The final sample size for this test equals 4,987 total firm-quarters, of which 1,894 are suspect repurchase firm-quarters. The final sample includes 139 firm-quarters designated as both $SUSPECT\_REPURCHASE1_{i,t} = 1$ and $SUSPECT\_ACCRUALS_{i,t} = 1$. Our results are qualitatively similar if we eliminate these firm-quarters from the sample.

IV. RESULTS

Descriptive Statistics

Table 1 presents descriptive statistics for the three samples relevant to our tests. Column 1 presents descriptive statistics for suspect repurchase firm-quarters ($SUSPECT\_REPURCHASE1_{i,t} = 1$), column 2 presents suspect accrual firm-quarters ($SUSPECT\_ACCRUALS_{i,t} = 1$), and column 3

*** Denotes the difference between suspect repurchase firm-quarters and either suspect discretionary accruals or the non-suspect control group are significant at less than 1 percent.

Variable Definitions:

$SUSPECT\_REPURCHASE1_{i,t} = 1$ where $ASIF\_FE1_{i,t}$ is $\geq -\$0.05$, but $< \$0.00$ *and* $ACTUAL\_FE_{i,t}$ is $\geq \$0.00$ but $\leq \$0.05$ for a firm-quarter, otherwise 0;

$SUSPECT\_ACCRUALS_{i,t} = 1$ where $ASIF\_FE\_ACCRUALS_{i,t} \geq -\$0.05$, but $< \$0.00$ *and* $ACTUAL\_FE_{i,t}$ is $\geq \$0.00$ but $\leq \$0.05$ for a firm-quarter, otherwise 0;

$HAQ_{i,t} = 1$ where the auditor is identified as the industry specialist, otherwise 0;

$REPURCHASE_{i,t-1(t-2)} = 1$ where a firm was a net repurchaser in the previous quarter ($t-1$) or two quarters prior ($t-2$), otherwise 0;

$Forecast\ Dispersion_{i,t}$ = standard deviation of analysts' forecasts that comprise the consensus analysts' forecasts. Firm-quarters with only one analyst forecast are removed from the test samples;

$Cash_{i,t-1}$ = cash and cash equivalents (CHEQ) at the beginning of the quarter scaled by total assets (ATQ);

$CAPEX_{i,t-1,t-4}$ = capital expenditures during the previous year ending at the beginning of the quarter scaled by total assets (ATQ);

$Dividend\ Yield_{i,t-1}$ = dividend payment (DIVY) during the previous year ending at the beginning of the quarter scaled by quarter end price (PRCCQ);

$Debt_{i,t-1}$ = total debt (DLTTQ + DLCQ) at the beginning of the quarter scaled by total assets (ATQ);

$Size_{i,t-1}$ = total assets (ATQ) at the beginning of the quarter;

$ROA_{i,t}$ = earnings before extraordinary items (IBQ) scaled by total assets (ATQ); and

$MTB_{i,t}$ = end-of-quarter market value of equity (CSHOQ * PRCCQ) scaled book value of equity (ATQ – LTQ – PSTKQ).

presents non-suspect control firm-quarters that, *ex post*, meet or beat consensus analysts' forecasts without accretive stock repurchases or discretionary accruals.

We find that 28 percent of suspect repurchase firm-quarters employ industry-specialist auditors (*HAQ*) versus 22 percent of suspect accrual firm-quarters and 24 percent of non-suspect control firm-quarters. These differences are statistically significant at the 0.01 level based on a t-test of differences in means.

We also find that 58 percent of suspect repurchase firm-quarters consummate a repurchase in the previous quarter ($REPURCHASE_{i,t-1} = 1$) as compared to 25 and 26 percent in the two comparison firm-quarters. Similar differences are present for repurchase behavior two quarters prior ($REPURCHASE_{i,t-2} = 1$). Combined, these findings indicate that suspect repurchase firm-quarters are approximately twice as likely to repurchase stock in previous quarters when compared to other firm-quarters in our sample.

For all other control variables, differences between suspect repurchase and suspect accrual firm-quarters are statistically significant at the 0.01 level. Similarly, all differences for the control variables between suspect repurchase firm-quarters and non-suspect control firm-quarters are statistically significant at the 0.01 level except for forecast dispersion. Most differences for the control variables between suspect discretionary accrual and the non-suspect control firm-quarters are also statistically significant, with the exception of previous quarter repurchases and capital expenditures. Combined, the significance of these differences suggests the need for multivariate testing.

Multivariate Analysis

Table 2 presents the results for the multivariate tests addressing H1. In Model 1, the coefficient on *HAQ* (β_1) is positive and significant, which supports our hypothesis that managers of firms with higher audit quality are more likely to use accretive stock repurchases to meet or beat analysts' forecasts. The marginal effect for *HAQ* indicates that high audit quality firm-quarters are 17 percent[12] more likely to make an accretive repurchase in comparison to firm-quarters that are able to meet or beat analysts' forecasts without an accretive repurchase *ex post*. These results are consistent with rejecting H1.

Table 2 also presents results for H2. In Model 2, the coefficient for *HAQ* (β_1) is negative and significant, providing evidence that firm-quarters with high audit quality are less likely to use discretionary current accruals to meet or beat analysts' forecasts. The marginal effect for *HAQ* suggests that firm-quarters with high audit quality are 11 percent less likely to use discretionary current accruals in comparison to firm-quarters that meet or beat analysts' forecasts without discretionary current accruals *ex post*.

In Model 3, we directly compare suspect repurchase firm-quarters with suspect accrual firm-quarters by including only observations for which $SUSPECT\_REPURCHASE1_{i,t} = 1$ or $SUSPECT\_ACCRUALS_{i,t} = 1$. The coefficient for *HAQ* (β_1) is positive and significant, which, along with results from Models 1 and 2, supports our hypothesis that firms with higher audit quality are more likely to use accretive stock repurchases and less likely to use discretionary current accruals to meet or beat analysts' forecasts. The marginal effect for *HAQ* indicates that firm-quarters with high audit quality are 23 percent more likely to use accretive stock repurchases than discretionary current accruals to meet or beat analysts' forecasts. The evidence presented in Table 2 is consistent with rejecting H2.

In addition to the results for high audit quality, most control variables are statistically significant in all three models. Prior repurchases are very strongly associated with suspect repurchases. As noted in prior research (Hribar et al. 2006), stock repurchases are serially correlated, which may confound our identification of suspect repurchase firm-quarters. We further address this concern through supplementary tests that explicitly control for expected repurchases.

Both suspect repurchase firm-quarters (Model 1) and suspect accrual firm-quarters (Model 2) are negatively associated with forecast dispersion, indicating that as the variance of analysts' forecasts increases, accretive repurchases and discretionary accruals are less likely to be used to

---

[12] We apply an odds ratio to evaluate the marginal effect of $HAQ_{i,t} = 1$ for all models. Since the variable of interest is dichotomous, the marginal effect is calculated as exp(coefficient estimate). Using a coefficient estimate = 0.16 as an example, exp(0.16) = 1.174 results in an odds ratio of 1.174/1.00. Interpreting this, firm-quarters engaging industry-specialist auditors (i.e., $HAQ_{i,t} = 1$) are 17 percent more likely to be identified as suspect repurchase firm-quarters.

---

*,**,*** Indicate significance at the 0.10, 0.05, and 0.01 levels, respectively, using two-tailed tests.

The likelihood ratio test statistic indicates the overall significance of the model and has a Chi-square distribution. All models are significant at less than 0.01. All variables are defined in Table 1. Results reflect the following logistic regressions:

Models 1 and 3:

$$\begin{aligned} SUSPECT\_REPURCHASE1_{i,t} = {} & \alpha + \beta_1 HAQ_{i,t} + \beta_2 Repurchase_{i,t-1} + \beta_3 Repurchase_{i,t-2} \\ & + \beta_4 Forecast\ Dispersion_{i,t} + \beta_5 Cash_{i,t-1} + \beta_6 CAPEX_{i,t-4,t-1} \\ & + \beta_7 Dividend\ Yield_{i,t-1} + \beta_8 Debt_{i,t-1} + \beta_9 Size_{i,t-1} + \beta_{10} Size^2_{i,t-1} + \beta_{11} Size^3_{i,t-1} \\ & + \beta_{12} ROA_{i,t} + \beta_{13} MTB_{i,t} + e_{i,t}. \end{aligned}$$

Model 2:

$$\begin{aligned} SUSPECT\_ACCRUALS_{i,t} = {} & \alpha + \beta_1 HAQ_{i,t} + \beta_2 Forecast\ Dispersion_{i,t} + \beta_3 Cash_{i,t-1} + \beta_4 CAPEX_{i,t-1} \\ & + \beta_5 Dividend\ Yield_{i,t-1} + \beta_6 Debt_{i,t-1} + \beta_7 Size_{i,t-1} + \beta_8 Size^2_{i,t-1} + \beta_9 Size^3_{i,t-1} \\ & + \beta_{10} ROA_{i,t} + \beta_{11} MTB_{i,t} + e_{i,t}. \end{aligned}$$

Each model sample reflects the following restrictions:

Model 1: Firm-quarters that meet or beat the consensus analysts' forecasts ($\$0.00 \leq ACTUAL_{FEi,t} \leq \$0.05$). The sample compares firm-quarters suspected of using accretive stock repurchases to meet or beat consensus analysts' forecasts to those that that meet or beat without accretive stock repurchases.

Model 2: Firm-quarters that meet or beat the consensus analysts' forecasts ($\$0.00 \leq ACTUAL_{FEi,t} \leq \$0.05$). The sample compares firm-quarters suspected of using discretionary accruals to meet or beat consensus analysts' forecasts to those that meet or beat without discretionary accruals.

Model 3: Firm-quarters identified as $SUSPECT\_REPURCHASE1_{i,t} = 1$, or $SUSPECT\_ACCRUALS_{i,t} = 1$. The sample compares firm-quarters suspected of using accretive stock repurchases to meet or beat consensus analysts' forecasts to firm-quarters suspected of using accruals to meet or beat consensus analysts' forecasts.

meet the consensus analysts' forecasts. In addition, both suspect repurchase and suspect accrual firm-quarters are positively associated with ROA, although ROA is much higher for suspect repurchase firm-quarters. The signs of cash, capital expenditures, dividend yield, and debt switch between Models 1 and 2, indicating that suspect repurchase firm-quarters exhibit lower levels of each, while suspect accrual firm-quarters exhibit higher levels of each when compared to non-suspect firm-quarters. Together, these findings suggest that firm characteristics are likely to affect firm choices between earnings management types, but also indicate possible underlying firm differences. We address this concern through supplementary tests that apply propensity score matching based on auditor industry specialization to better control for firm differences.

Supplementary Tests

Controlling for Expected Repurchases

Our main tests estimate pre-repurchase forecast error (i.e., *ASIF_FE1*) assuming that firms' open-market repurchases are not anticipated by analysts and investors. If firms previously announce open-market repurchase programs or if analysts anticipate the serial correlation in stock repurchase behavior, then our approach likely understates analysts' and investors' repurchase expectations. Our main tests control for this by including prior stock repurchases in the suspect repurchase models. However, to further address this concern, we next directly estimate expected repurchases for use in the suspect repurchase models (see Hribar et al. 2006, 18–19).

We follow Hribar et al. (2006) and estimate expected repurchases by a firm in a given quarter using a two-stage approach that models expected repurchases as the product of the estimated probability that firms will repurchase stock (stage 1) and the expected level of repurchases given that one occurs (stage 2). The first-stage estimation uses both repurchase and non-repurchase firms to estimate a repurchase expectation for every firm-quarter in the sample. The first stage models the repurchase decision as a binary variable, and estimates the following probit model:

$$\begin{aligned} REPURCHASE_{i,t} = {} & \alpha + \beta_1 Repurchase_{i,t-1} + \beta_2 Repurchase_{i,t-2} + \beta_3 Cash_{i,t-1} \\ & + \beta_4 CAPEX_{i,t-4,t-1} + \beta_5 Dividend\,Yield_{i,t-1} + \beta_6 Debt_{i,t-1} + \beta_7 Size_{i,t-1} \\ & + \gamma_k Industry_{i,k} + \delta_j Year_{i,j} + \varphi_q Qtr_{i,q} + e_{i,t}, \end{aligned} \tag{3}$$

where $REPURCHASE_{i,t}$ equals 1 if firm i repurchased shares during quarter t, and 0 otherwise. Independent variables are measured at the beginning of the quarter when expectations are more likely formed about potential stock repurchases. Most control variables are the same as those used in the suspect repurchases model. $Industry_{i,k}$, $Year_{i,j}$, and $Qtr_{i,q}$ are included as fixed effects.

Untabulated results for the first-stage regression reveal that the probability of a repurchase is positive and significantly associated with prior repurchases, dividend yield, and size, and negative and significantly associated with cash, capital expenditures, and debt. The pseudo-R^2 from the first-stage analysis is 27.7 percent.

The second-stage model provides an estimate for dollars spent on stock repurchases based on firm characteristics conditioned on the probability that a repurchase occurs. The second-stage regression is similar to the first-stage, except that the actual dollar value of stock repurchases replaces the binary repurchase variables from the first stage and information about the probability of a repurchase is incorporated into the model. Information about the probability of a repurchase for all firms, not just repurchasing firms, is incorporated in the second-stage regression through two variables calculated from the first stage, the standard normal probability density function (φ) and the cumulative density function (Φ). The variable φ is included in the second-stage regression, while Φ is multiplied by each of the independent variables from the first stage. Untabulated results for the second-stage regression show that all variables except capital expenditures are significantly related in the expected direction to the dollar value of stock repurchases. The adjusted R^2 in the second stage is 57.1 percent.

The second-stage estimates generate an unconditional expectation of the dollar amount of repurchases for firm-quarters based on information known at the beginning of each quarter. The expected number of shares repurchased is calculated by dividing the estimated dollar amount of shares repurchased by the beginning of the quarter stock price. From this estimate of the expected number of shares repurchased, we create a second "as-if" EPS estimate that incorporates expected stock repurchase activity:

$$ASIF\_EPS2_{i,t} = \frac{(NI_{i,t} + C_{i,t})}{\left[SHARESOUT_{i,t-1} + (0.5*SHARESISSUED_{i,t}) - \left(0.5*E(REPURCHASE_{i,t})\right)\right]},$$

where $E(REPURCHASE_{i,t})$ is the expectation of shares to be repurchased at the beginning of the quarter. *ASIF_EPS2* is similar to *ASIF_EPS1*, except that it removes the EPS effects of expected repurchases. The difference between reported EPS and *ASIF_EPS1* includes the EPS effects of both expected and unexpected repurchases, whereas the difference between reported EPS and *ASIF_EPS2* only reflects the EPS effects of unexpected repurchases.

To obtain the pre-repurchase forecast error based on unexpected repurchases, we isolate the impact of unexpected stock repurchases on EPS (*EPSImpact2*) by comparing *ASIF_EPS2* and reported EPS, where:

$$EPSImpact2_{i,t} = ReportedEPS_{i,t} - ASIF\_EPS2_{i,t}.$$

EPSImpact2 is positive for accretive stock repurchases and negative for non-accretive stock repurchases.

The pre-repurchase forecast error based on unexpected repurchases is calculated as the actual forecast error less the EPS effect of unexpected repurchases. Specifically:

$$ASIF\_FE2_{i,t} = ACTUAL\_FE_{i,t} - EPSImpact2_{i,t}.$$

ASIF_FE2 is negative for firm-quarters that would have missed consensus analysts' forecasts absent the effects of accretive stock repurchases. For firms that do not repurchase stock, *ASIF_FE2* equals *ACTUAL_FE*.

Finally, we define suspect repurchases as those that would have missed analysts' forecasts by five cents or less, but are able to meet or beat forecasts by no more than five cents with unexpected stock repurchases. We construct an indicator variable ($SUSPECT\_REPURCHASE2_{i,t} = 1$) as an alternative measure for suspect repurchases based on unexpected repurchases, where *ASIF_FE2* is $\geq -\$0.05$ and $< \$0.00$ *and ACTUAL_FE* is $\geq \$0.00$ and $\leq \$0.05$ for a firm-quarter. *SUSPECT_REPURCHASE2* is equal to 0 for all other firm-quarters.

Table 3 replicates our main tests for H1 and H2, but substitutes *SUSPECT_REPURCHASE2* for *SUSPECT_REPURCHASE1* to control for expected repurchases. The results from these supplementary tests are consistent with our main tests. In Model 4, the coefficient on *HAQ* (β_1) is positive and significant, which provides support that managers of firms with higher audit quality are more likely to use accretive stock repurchases to meet or beat analysts' forecasts. In Model 5, the coefficient for *HAQ* (β_1) is negative and significant, providing evidence that firm-quarters with high audit quality are less likely to use discretionary current accruals to meet or beat analysts' forecasts. Finally, in Model 6, the coefficient for *HAQ* (β_1) is positive and significant, which supports our hypothesis that firms with higher audit quality are more likely to use accretive stock repurchases and less likely to use discretionary current accruals to meet or beat analysts' forecasts.

*,**,*** Indicate significance at the 0.10, 0.05, and 0.01 levels, respectively, using two-tailed tests.

The likelihood ratio test statistic indicates the overall significance of the model and has a Chi-square distribution. All models are significant at less than 0.01. All variables are as defined in Table 1, except *SUSPECT_REPURCHASE2*, which is equal to 1 where $ASIF\_FE2_{i,t}$ is ≥ −\$0.05, but < \$0.00 *and* $ACTUAL\_FE_{i,t}$ is ≥ \$0.00, but ≤ \$0.05 for a firm-quarter, otherwise 0.

Models 4–6 mirror Table 2, Models 1–3. Each model sample reflects the same restrictions identified in Table 2 except the restrictions to *SUSPECT_REPURCHASE2*.

Propensity Score Matching

Our main tests use control variables to reduce the effects of firm characteristics on the association between suspect repurchases, suspect accruals, and high audit quality. However, the results from our main tests may still be influenced by fundamental differences in firm characteristics. Prior research (Lawrence et al. 2011; Armstrong et al. 2010) finds that the regression framework is subject to misspecification of the functional relationship between control variables and the dependent variable for different treatment levels and recommends using propensity score matching to address this concern. In our study, size is of particular concern since industry-specialist auditors are identified based on market share. Therefore, we employ propensity score matching to match firms with industry-specialist auditors to firms without industry-specialist auditors based on relevant observable firm characteristics.

First, following Gul et al. (2009), we estimate propensity scores using a logistic regression in which the dependent variable is either an industry-specialist auditor (1) or not an industry-specialist auditor (0). We model the choice of an industry-specialist auditor based on size, debt, return on assets, market-to-book, asset turnover, litigation risk, lagged absolute value of discretionary

---

*,**,*** Indicate significance at the 0.10, 0.05, and 0.01 levels, respectively, using two-tailed t-tests.

The table presents means and differences in means for firms with *HAQ* and propensity score matched firms without *HAQ*. Using the full sample from the main tests in Table 2, we match *HAQ* firms, without replacement, to non-*HAQ* firms with the closest propensity score and within a maximum distance of 0.03.

[a] $Size^2$ is scaled by one million and $Size^3$ is scaled by one billion.

All other variables are defined in Table 1.

Variable Definitions:

Asset Turnover = quarterly sales divided by total assets;

Litigation = 1 for firms with the following SIC codes: (2833–2836), (3570–3577), (3600–3674), (5200–5961), or (7370–7370), otherwise 0;

Abs. DACC = previous quarter's absolute value of discretionary accruals; and

Age = log of the number of years a firm has been on Compustat beginning with 1950.

accruals, age, industry, and year. Next we match, without replacement, an industry-specialist firm to the non-industry-specialist firm with the closest propensity score within a maximum distance of 0.03. This results in 5,153 matched pairs.

Table 4 reports tests of differences in means of observable firm characteristics between the *HAQ* and matched non-*HAQ* firms for suspect repurchases and suspect accruals. The two-tailed t-tests of differences in means indicate that none of the observable firm characteristics are significantly different between the sample and control firms, suggesting that the firms are matched appropriately. As described next, we find that firms with industry-specialist auditors are more likely to use accretive repurchases to meet or beat analysts' forecasts than firms with non-industry-specialist auditors. The difference between *HAQ* and matched non-*HAQ* firms for *SUSPECT_REPURCHASE1* (*SUSPECT_REPURCHASE2*) indicates that firms with industry-specialist auditors execute 14.5 percent (35.7 percent) more suspect repurchases than firms without industry-specialist auditors. The p-values for the difference in means between *HAQ* and matched non-*HAQ* firms for *SUSPECT_REPURCHASE1* and *SUSPECT_REPURCHASE2* are 0.095 and 0.012, respectively. Consistent with a trade-off between accretive repurchases and accrual-based earnings management, we find that firms with industry-specialist auditors use 13.5 percent less suspect accruals to meet or beat analysts' forecasts than the same matched non-industry-specialist auditor firms. The p-value of the difference in means for *SUSPECT_ACCRUALS* is 0.007. The evidence from propensity score matching supports our main results and helps alleviate concerns that differences in observable firm characteristics are driving our results.

V. SENSITIVITY TESTS

One concern is that our main tests could be capturing a spurious relation between high audit quality and accretive stock repurchases and discretionary accruals. We address this issue in two ways. First, we test whether there is a relation between accretive stock repurchases and discretionary current accruals absent incentives to meet or beat analysts' forecasts. We identify both accretive stock repurchase firm-quarters and EPS increasing discretionary current accruals not classified as suspect in our main tests. In other words, we test whether our hypothesized trade-off persists for non-suspect repurchase and non-suspect accrual firm-quarters. Untabulated results show that high audit quality is not significantly related to non-suspect repurchase or accrual firm-quarters, providing evidence that our main tests are not capturing a general relation.

Second, we adopt an approach similar to Ayers et al. (2006) by examining whether a trade-off between suspect repurchases and suspect accruals exists where the change in EPS is the difference between meeting or beating *pseudo* earnings targets set at five cents above or below analysts' forecasts. If the results from our main tests are unrelated to analysts' forecasts, we would expect the results around *pseudo* targets to be similar to the results occurring around analysts' forecasts. Unlike the results from our main tests, untabulated results for high audit quality are insignificant using *pseudo* targets, providing further evidence that efforts to meet or beat analysts' forecasts are an important aspect of our study.

A second concern stems from the fact that auditor scrutiny is likely more rigorous during the fourth quarter (Brown and Pinello 2007) and, therefore, fourth quarter observations could be driving our main results. However, audit quality is likely to affect the first three quarters for at least two reasons. First, technological advancements in auditing reduce the seasonality of auditing by facilitating timely interim reviews and reducing year-end workloads (Shu 2000). Second, managers' accrual choices during the first three quarters are likely affected by expectations of higher audit scrutiny at year-end. We ensure that our main results are not driven by observations from the fourth quarter by re-estimating our main tests using only the first three fiscal quarters during which auditor oversight may be less stringent. Results are qualitatively similar for the first three quarters, which provides evidence that high audit quality is associated with our suggested trade-off even in quarters with less stringent auditor scrutiny.

VI. IMPLICATIONS AND CONCLUSION

We examine whether audit quality affects managers' choices between accrual-based earnings management and accretive stock repurchases. We provide consistent evidence that firms that engage high-quality auditors are more likely to use accretive stock repurchases and less likely to manage accruals to meet or beat consensus analysts' forecasts. Combined, our findings suggest that managers faced with high audit quality trade off the use of accretive stock repurchases with accrual-based earnings management to meet or beat analysts' forecasts.

Our findings have at least three implications for corporate governance. First, our findings provide evidence that the decision to hire high audit quality to combat accrual-based earnings management is associated with an unintended consequence: the increased use by managers of at least one real earnings management mechanism—accretive stock repurchases. Firms choose high audit quality to signal earnings quality and corporate governance effectiveness. This signal becomes obfuscated when the use of real earnings management is elevated.

Second, if managers circumvent high audit quality through the use of this real earnings management technique, then other governance mechanisms, especially those limiting management's ability to use real earnings management to influence firm performance measures, might be considered concurrently with the decision to engage a high-quality auditor. Corporate boards and audit committees may wish to consider compensation-related issues and other contractual features for managers that constrain firm value-decreasing behaviors of management.

Finally, the use of accretive repurchases to meet or beat EPS benchmarks potentially deviates from "business as usual," which may have negative consequences to the short- and long-term performance of the firm. Often, accretive stock repurchases involve a substantial number of shares and firms face significant opportunity costs from the loss of resources used in accretive stock repurchases. This is especially problematic when repurchases alter normal business practices. Although not formally tested in this paper, accretive repurchases used as a real earnings management tool could potentially have unfavorable implications for a firm's current and future operating performance and could impose unnecessary costs on the firm and its shareholders.[13]

APPENDIX A
VARIABLE DESCRIPTIONS

$Abs.\ DACC_{i,t-1}$ = absolute value of a firm's previous quarter discretionary accruals;

$ACTUAL\_FE_{i,t}$ = firm's reported EPS minus its final consensus analysts' forecast;

$Age_{i,t}$ = log of the number of years a firm has been on Compustat, beginning in 1950;

$ASIF\_EPS1_{i,t}$ = firm's estimated EPS absent accretive stock repurchases calculated as:

$$\frac{NI_{i,t} + C_{i,t}}{SHARESOUT_{i,t-1} + 0.5*SHARESISSUED_{i,t}};$$

$ASIF\_EPS2_{i,t}$ = firm's estimated EPS absent accretive stock repurchases that incorporates expected repurchases, calculated as:

$$\frac{(NI_{i,t} + C_{i,t})}{\left[SHARESOUT_{i,t-1} + (0.5*SHARESISSUED_{i,t}) - \left(0.5*E(REPURCHASE_{i,t})\right)\right]};$$

$ASIF\_EPS\_ACCRUALS_{i,t}$ = firm's estimated EPS absent current discretionary accruals, net of income taxes, calculated as:

$$\frac{NI_{i,t} - DACC_{i,t}(1 - T_{i,t})}{Weighted\ Average\ SHARESOUT_{i,t}};$$

$ASIF\_FE1_{i,t}$ = firm's estimated pre-repurchase forecast error, calculated as: $ACTUAL\_FE_{i,t} - EPSImpact1_{i,t}$;

$ASIF\_FE2_{i,t}$ = firm's estimated pre-repurchase forecast error that incorporates expected repurchases, calculated as: $ACTUAL\_FE_{i,t} - EPSImpact2_{i,t}$;

$ASIF\_FE\_ACCRUALS_{i,t}$ = firm's estimated pre-discretionary current accrual forecast error, calculated as: $ACTUAL\_FE_{i,t} - EPSImpact1\_ACCRUALS_{i,t}$;

$Asset\ Turnover_{i,t}$ = firm's quarterly sales divided by total assets (ATQ);

$C_{i,t}$ = estimated forgone dollar return on cash used for accretive stock repurchases. When a firm has excess cash, the forgone return is estimated as excess cash multiplied by the three-month Treasury bill rate. Excess cash is estimated as cash balances in excess of 6 percent of assets for retail firms and 2 percent of assets for all other firms (Copeland et al. 2000). If excess cash is less than the repurchase dollar amount, then the forgone return is estimated as the firm's average interest rate multiplied by the incremental funds borrowed;

$CAPEX_{i,t-4,t-1}$ = firm's capital expenditures during the previous year ending at the beginning of the quarter, scaled by total assets (ATQ);

$Cash_{i,t-1}$ = firm's cash and cash equivalents (CHEQ) at the beginning of the quarter, scaled by total assets (ATQ);

$Current\ Accruals_{i,t}$ = difference between quarterly income before extraordinary items (IBQ) and quarterly operating cash flows (OANCFY, adjusted to quarterly) less depreciation and amortization expense (DPQ);

$DACC_{i,t}$ = difference between the actual reported current accruals and the estimated current accruals from the current discretionary accrual model rescaled by lagged total assets ($ATQ_{i,t-1}$);

$Debt_{i,t-1}$ = firm's total debt (DLTTQ + DLCQ) at the beginning of the quarter, scaled by total assets (ATQ);

$Dividend\ Yield_{i,t-1}$ = firm's dividend payment during the previous year ending at the beginning of the quarter, scaled by its quarter-end share price (PRCCQ);

$EPSImpact1_{i,t}$ = effect of share repurchases on EPS, calculated as: $ReportedEPS_{i,t} - ASIF\_EPS1_{i,t}$;

$EPSImpact2_{i,t}$ = effect of unexpected share repurchases on EPS, calculated as: $ReportedEPS_{i,t} - ASIF\_EPS2_{i,t}$;

$EPSImpact1\_ACCRUALS_{i,t}$ = effect of discretionary accruals on EPS, calculated as: $ReportedEPS_{i,t} - ASIF\_EPS\_ACCRUALS_{i,t}$;

$E(REPURCHASE_{i,t})$ = expected number of shares to be repurchased at the beginning of the quarter based on the two-stage estimation procedure detailed in the "Controlling for Expected Repurchases" section;

$Forecast\ Dispersion_{i,t}$ = standard deviation of analysts' forecasts that comprise the consensus forecast;

$HAQ_{i,t}$ = 1 where the auditor is identified as the industry specialist, otherwise 0;

$Litigation_{i,t}$ = 1 for firms with the following SIC codes (2833–2836), (3570–3577), (3600–3674), (5200–5961), or (7370), otherwise 0;

$MTB_{i,t}$ = firm's end-of-quarter market value of equity (CSHOQ * PRCCQ), scaled by its book value of equity (ATQ − LTQ − PSTKQ);

$NI_{i,t}$ = firm's reported earnings before extraordinary items available to common shareholders for the firm-quarter (IBCOMQ);

$ReportedEPS_{i,t}$ = firm's earnings per share as reported for the quarter;

$REPURCHASE_{i,t,(t-1),\{t-2\}}$ = 1 where a firm was a net repurchase in the previous quarter (t–1) or two quarters prior (t–2), otherwise 0;

$ROA_{i,t}$ = earnings before extraordinary items (IBQ), scaled by total assets (ATQ);

$SHARESISSUED_{i,t}$ = actual or estimated number of common stock shares issued during a firm-quarter, depending on data availability;

$SHARESOUT_{i,t-1}$ = reported number of diluted common shares outstanding if analysts' forecast diluted EPS, otherwise primary common shares outstanding, at the beginning of the firm-quarter;

$Size_{i,t-1}$ = firm's total assets (ATQ) at the beginning of the quarter;

$SUSPECT\_REPURCHASE1_{i,t}$ = indicator variable indicating whether the firm meets or beats analysts' consensus forecasts using share repurchases, equal to 1 if *ASIF_FE1* is $\geq -\$0.05$, but $< \$0.00$ *and ACTUAL_FE* is $\geq \$0.00$, but $\leq \$0.05$, otherwise 0;

$SUSPECT\_REPURCHASE2_{i,t}$ = indicator variable indicating whether the firm meets or beats analysts' consensus forecasts using unexpected share repurchases, equal to 1 if *ASIF_FE2* is $\geq -\$0.05$ and $< \$0.00$ *and ACTUAL_FE* is $\geq \$0.00$ and $\leq \$0.05$, otherwise 0;

$SUSPECT\_ACCRUALS_{i,t}$ = indicator variable indicating whether the firm meets or beats analysts' consensus forecasts using discretionary accruals, equal to 1 if *ASIF_FE_ACCRUALS* $\geq -\$0.05$, but $< \$0.00$ *and ACTUAL_FE* is $\geq \$0.00$, but $\leq \$0.05$, otherwise 0; and

Weighted Average $SHARESOUT_{i,t}$ = weighted average diluted common shares outstanding if analysts' forecast diluted EPS (CSHFDQ), otherwise primary common shares outstanding (CSHPRQ).

Flora H. Zhou
University of Illinois at Urbana–Champaign

ABSTRACT: In an environment where three-person groups develop a creative solution to an important problem, we examine whether the efficacy of either individual- or group-based creativity-contingent incentives depends on whether they take the piece-rate or tournament form. We predict and find that group (intergroup) tournament pay increases group cohesion and collaborative efforts, which ultimately lead to a more creative group solution, relative to group piece-rate pay. While individual (intragroup) tournament pay increases individual efforts, we find that it does not enhance the creativity of group solutions relative to individual piece-rate pay. Our results advance the burgeoning management accounting literature on creativity-contingent incentives by demonstrating that reward systems are more likely to promote group creativity through collaborative efforts rather than independent individual efforts. We also provide important insights into when and why tournament pay can boost group creativity in organizations. In doing so, we contribute to a better understanding of observations from practice suggesting that organizations valuing creativity often induce intergroup competition.

We have received helpful suggestions on previous drafts from Mark Bagnoli, Robert Bowen, Willie Choi, Mary Curtis, Harry Evans, Sue Haka, Steve Kachelmeier, Ranjani Krishnan, Clive Lennox, Stijn Masschelein, Ed O'Donnell, Mark Peecher, Mark Penno, Casey Rowe, D. I. INTRODUCTION

Organizations often look to employee groups to provide a creative solution to an important problem (Nussbaum 2005; Thompson and Choi 2006; Adler and Chen 2011). As such, a challenge for management accountants is designing performance evaluation and reward systems to promote group creativity (Kaplan and Norton 1996, Ch. 5). While a frequently proposed solution to this challenge is to reward either groups for the creativity of their solution or individuals for the creativity of their input to the group solution, prior research suggests creativity-contingent incentives often do not lead to the desired result. For example, consistent with theory suggesting that creativity is a dimension of performance that does not respond well to individuals' independent efforts (Amabile 1996), prior research demonstrates that reward systems that motivate individuals to independently work harder at being creative often do not lead to more creative output (Kachelmeier et al. 2008; Kachelmeier and Williamson 2010). Tying rewards to a group-based measure of creativity can potentially enhance group creativity by increasing collaborative efforts (Toubia 2006). However, prior research highlights that groups often do not capitalize on these opportunities due to obstacles such as evaluation apprehension (i.e., anxieties that fellow group members will evaluate one's ideas unfavorably) and free-riding (which is exacerbated by the considerable cognitive effort required to process, synthesize, and build on the diverse ideas of others) (Paulus 2000; Paulus and Yang 2000).

These conclusions, however, are limited by the fact that prior research often considers only a single form of creativity-contingent incentive—most often piece-rate—where pay for either groups or individuals strictly increases in creativity (Sprinkle 2008). However, tournament pay, which can induce either intergroup or intragroup competition, is quite pervasive in organizations (Lambert et al. 1993; McGregor 2006). Moreover, in environments where a measure of group (individual) creativity is available, the decision of whether to induce intergroup (intragroup) competition or make pay an increasing function of the creativity measure is often an important choice faced by managers. As such, we examine whether moving from the piece-rate to the tournament form of compensation better promotes group creativity across environments in which individuals receive pay based on either (1) the creativity of the group's solution, or (2) the creativity of their individual input to the group's solution.

Drawing on theory from psychology, we develop a process model suggesting that group tournament pay helps overcome obstacles, such as those noted earlier, that would otherwise limit the effectiveness of creativity-contingent incentives relative to group piece-rate pay. When a group feels challenged or threatened by outsiders, such as other groups competing with it for an organization's scarce resources, members feel a greater sense of cohesion or solidarity with one another. Members of cohesive groups feel stronger psychological bonds with each other and believe that other members are more open to their ideas, which enhances the ease with which group members share ideas, thus reducing evaluation apprehension. Moreover, members of cohesive groups feel more united in trying to achieve group objectives and, therefore, work harder toward achieving them, which decreases free-riding (Brewer 1979; Tajfel and Turner 1986; van Knippenberg 2000; Bornstein 2003). Thus, to the extent that intergroup competition enhances cohesion, we expect that group members will not only more freely share their ideas, but also they will exert the cognitive efforts necessary to process, synthesize, and build on each others' ideas, which can ultimately enhance the creativity of a group's solution (Tagger 2002; Van der Vegt and Bunderson 2005).

In addition to testing our process model, which suggests that tournament pay increases the efficacy of group-based creativity-contingent incentives, we further validate our model by examining whether tournament pay increases the efficacy of individual-based creativity-contingent incentives. Relative to individual piece-rate pay, research suggests that intragroup competition sparked by individual tournaments motivates more independent, individual efforts, to the detriment of collaboration (Drake et al. 1999). However, to the extent that (1) research suggesting that one cannot be more creative by simply independently working harder generalizes to a group setting, and (2) reward systems better motivate group creativity by increasing cohesion (as our process model suggests) rather than simply motivating greater effort *per se*, individual tournament pay will likely not increase the creativity of a group's solution relative to individual piece-rate pay. As such, we predict that group tournament pay will increase and individual tournament pay will not increase the efficacy of creativity-contingent incentives relative to group and individual piece-rate pay, respectively.

To test our predictions, we use a laboratory experiment in which three-person groups of undergraduate students developed a creative solution (i.e., a solution that is "original, innovative, and implementable within a reasonable budget") to an assigned campus problem. During the idea generation and development phase, groups utilized a computer program that allowed participants to easily generate new ideas and develop others' and individuals' own ideas. Groups then selected one of the developed ideas to serve as their group solution.

We manipulated two factors between-subjects at two levels each. First, we manipulate the *level of incentives* by tying participant pay to a measure of either the creativity of the group's solution or the creativity of individual input to the group's solution, both as assessed by an independent panel of three raters. Second, we manipulate the *form of incentives* by providing participants with either a linear piece-rate based on their assigned measure or a winner-take-all tournament. The winner-take-all tournament takes the form of either an intergroup tournament, where groups competed against two other groups in their session based on the creativity of the group's solution, or an intragroup tournament, where individuals competed against their other two group members based on the creativity of their individual input to the group solution. Across all four conditions, we held average participant compensation constant.

Our results support our predictions. Group tournament pay leads to more creative group solutions than does group piece-rate pay. We further show that group cohesion encompassing measures regarding group members' psychological bond, openness to each others' ideas, and the extent that group members feel united in achieving group objectives partially mediates the positive creativity effect of group tournament pay relative to group piece-rate pay. Individual tournament pay fails to generate more creative group solutions relative to individual piece-rate pay, either in our initial experiment where we rewarded individuals based solely on the creativity of their inputs to the selected group solution or in a supplemental experiment where we rewarded individuals based on the creativity of their input to all group ideas.

In addition to creativity ratings and self-reported measures, we also explore how our experimental conditions affect within-group interactions while generating initial ideas, developing these ideas, and selecting one of these ideas as the group solution. While groups across all conditions consider a similar number/diversity of initial ideas and exhibit similar propensities to select their most creative idea as the group solution, we observe important differences in how groups develop their ideas. On the one hand, group tournament pay increases the extent to which group members build on each others' thoughts and ideas when developing proposals relative to those in the group piece-rate condition. On the other hand, individual tournament pay increases the extent to which individuals build on their own thoughts and ideas relative to the average of the other conditions, but consistent with prior research, these independent individual efforts do not appear to enhance individual or group creativity.

Our study makes important contributions. First, we show that tournament pay that induces intergroup competition can help overcome obstacles identified by prior research that limit the effectiveness of creativity-contingent incentives. In doing so, we also shed light on the process of idea generation, development, and selection that takes place within groups under various reward systems. We use a unique software program to capture a rich, objective dataset that reflects these within-group processes, and our analysis of this dataset yields important insights into how aspects of these creative processes differ under various incentive schemes. Although research from individual settings often suggests that creativity is invariant to reward system design, our results demonstrate that reward systems can play a vital role in promoting group creativity by encouraging individuals to collaborate and build on the diverse ideas of others.

Second, our study contributes more generally to research investigating the efficacy of tournament pay (e.g., Young et al. 1993; Drake et al. 1999; Hannan et al. 2008). By simultaneously studying how group and individual tournaments affect group creativity as well as illuminating the processes through which intergroup competition promotes higher group performance, we gain a better understanding of when tournament pay can be effective (Luft and Shields 2003). For example, while Drake et al. (1999) suggest that tournament pay does not lead to higher group performance on a collaborative task, they focus solely on individual (intragroup) tournaments.

Our results also contribute to a better understanding of observations from practice. Case and field studies demonstrate that organizations seeking group creativity often induce intergroup competition (Amabile and Gryskiewiecz 1987; Arnold 1998; Simons 2000). We develop and test a theory that can help explain why these practices have evolved in organizations.

We describe the background of our study and develop hypotheses in Section II. Section III explains our experimental method and design, Section IV presents results, and Section V concludes.

II. BACKGROUND, THEORY, AND HYPOTHESES

Background

Creative organizational endeavors, such as developing a proposal to address an important organizational problem, often take place in group settings (Thompson and Choi 2006). In a group setting, creativity can arise not only from the innovativeness of an individual group member, but also through collaborative efforts of multiple group members. The opportunity to observe, synthesize, and build on each others' ideas can make group members see the situation from multiple perspectives and thus increase the creativity of individual inputs to the group (Toubia 2006). Moreover, groups can coordinate their efforts to further develop the most creative individual inputs to transform them into a more creative group solution (Adler and Chen 2011).

A potential technique for promoting group creativity is to tie employee pay to a group-based measure of creativity (Toubia 2006).[1] However, prior research identifies obstacles that potentially limit the effectiveness of group-based incentives. For example, evaluation apprehension can limit individual contributions in group-creativity settings. That is, many individuals are anxious about sharing creative ideas, fearing that others will evaluate them unfavorably (Paulus et al. 2006). Moreover, even to the extent that individuals share their ideas, free-riding can limit the benefits from the diverse ideas of group members (Paulus 2000). That is, individuals under group-based creativity-contingent incentives are typically not willing to exert the significant cognitive efforts required to process, synthesize, and build on the diverse ideas of their group members (Paulus and Yang 2000).

---

[1] In our setting, the group's objective is to develop a single creative solution. Throughout the remainder of the paper, we refer to the creativity of this solution as group creativity. We operationalize group creativity in this fashion for two primary reasons. First, given the amount of time we can reasonably keep participants in our laboratory setting, asking them to submit one solution rather than many solutions has a greater chance of encouraging collaboration among members (i.e., building on each other's inputs while developing solutions), which allows us to more powerfully test our theory. Second, because evaluating ideas is costly for management, organizations often require groups to put forth only their best or most creative solution to the problem being addressed (Sutton and Hargadon 1996).

To overcome these concerns, organizations may have the opportunity to measure and reward creativity at the individual rather than the group level. That is, organizations may tie rewards to the creativity of employee input to the group in order to motivate employees to independently work harder at being creative (Pirola-Merlo and Mann 2004). However, prior research suggests that obstacles may also limit the effectiveness of individual-based creativity incentives. For example, theory suggests that creativity does not arise simply from motivating individuals to independently work harder (Amabile 1996).[2] Recent research in accounting supports this premise. For example, in settings without opportunities for collaboration, reward systems motivating individuals to work harder at being creative often do not lead to more creative output (Kachelmeier et al. 2008; Kachelmeier and Williamson 2010).

While prior research suggests that obstacles limit both individual- and group-based creativity-contingent incentives, prior research typically only considers a single form of creativity-contingent incentive, something akin to piece-rate pay where better performance results in strictly higher rewards (Sprinkle 2008). We next develop a theory-based process model suggesting that group-based tournaments can help overcome obstacles found to limit the effectiveness of creativity-contingent incentives and ultimately lead to a more creative group solution relative to group piece-rate pay.[3] Figure 1 summarizes this process model.

Group Tournament Pay Relative to Group Piece-Rate Pay

In this section, we discuss the effects of group tournament pay that induces intergroup competition relative to group piece-rate pay. An example of a tournament scheme that induces intergroup competition in practice is a competitive budgeting system that funds and provides higher pay to the most creative production teams (Kanter et al. 1997; Simons 2000; Nussbaum 2005). As another example, organizations such as Boeing and DuPont post pressing problems and request teams to submit proposals to address them. Each team is often constrained to submit a single proposal in competition with other teams for a pre-specified cash reward (Brabham 2008). We next develop how organizations can use intergroup competition to help overcome obstacles that limit the effectiveness of group-based creativity-contingent incentives.

Theory in psychology posits that when a group is challenged or threatened by outsiders, such as other groups competing with it for an organization's scarce resources, group members feel an increased sense of cohesion or solidarity with one another (Fiedler 1967; Friedkin 2004). These feelings result because intergroup competition makes salient in-group and out-group categorizations

---

[2] Of course, measuring creativity at the individual level would likely also be more costly than measuring creativity at the group level. However, using a laboratory experiment allows us to control for these measurement issues so that we can better isolate the behavioral effects of individual relative to group-based creativity-contingent incentives.

[3] Given that prior research identifies obstacles that limit the effectiveness of both individual- and group-based creativity-contingent incentives, we do not make a prediction as to the main effect of incentive level (individual versus group) on group creativity. Rather, our focus is on the potential differential effect of incentive form (piece-rate versus tournament) on group relative to individual creativity-contingent incentives. In environments where a measure of group (individual) creativity is available, we examine the implications of either using the measure to induce intergroup (intragroup) competition or making pay an increasing function of this measure.

and thus encourages group members to categorize themselves as a single group rather than a collection of individuals (Tajfel and Turner 1979; Turner et al. 1987). Supporting this theory, prior empirical research demonstrates that competition and rivalry among groups enhance group solidarity and the psychological bond among group members (e.g., Bornstein and Erev 1994; Mulvey and Ribbens 1999).

To the extent that group tournament pay enhances group cohesion relative to group piece-rate pay, it can help mitigate evaluation apprehension and free-riding that can limit the effectiveness of group-based creativity incentives. First, members of cohesive groups feel that other group members are more open to their ideas and, thus, feel less anxious that group members will negatively evaluate their thoughts and ideas. Ultimately, these attitudes could lead members to more willingly share their ideas about problems faced by the group and comment on the thoughts and ideas of others.

Second, members of cohesive groups feel more united in trying to achieve group objectives. That is, individuals are more likely to adopt group goals as personal goals, thus blurring the distinction between self-interest and group interest (Bornstein and Erev 1994; Kramer and Brewer 1984). This attitude could drive them to exert greater effort to achieve collective goals, focus on collective outcomes rather than individual rewards, and maintain their commitment to the collective even when it does not benefit them individually (Brewer 1979; Chen et al. 1998; van Knippenberg 2000; Towry 2003; Ellemers et al. 2004). If so, then individuals in a group-creativity setting could be more willing to exert the cognitive efforts necessary to process, synthesize, and build on each others' ideas.

Ultimately, the more open exchange of ideas and efforts to synthesize and build on these ideas can enhance the effective integration of divergent perspectives and lead to more creative individual inputs (Paulus 2000; Van der Vegt and Bunderson 2005). Moreover, because group members are more receptive to each others' ideas, they can better coordinate efforts to further develop or build on the most creative individual inputs to transform them into more creative group solutions (Tagger 2002).

Individual Tournament Pay Relative to Individual Piece-Rate Pay

In this section, we discuss the effects of individual tournament pay based on intragroup competition relative to individual piece-rate pay. Examples of individual-based (intragroup) tournaments, in which individuals compete against members of their own departments or teams, include competition for scarce promotion opportunities or a fixed bonus pool to be distributed among managers (Milgrom and Roberts 1992, Ch. 11). Relative to individual piece-rate pay, research suggests that intragroup competition sparked by individual tournaments motivates more independent individual efforts. For example, in a laboratory experiment where three-person groups each produced a subcomponent of a castle from toy blocks that can then be joined together, Drake et al. (1999) identified conditions where intragroup tournament pay increased independent individual efforts such that individuals produced more units of their castle subcomponent.

These individual efforts, however, are unlikely to facilitate group cohesion and collaborative efforts among group members, which are essential for group creativity. As such, examining the effects of individual tournament pay in a group-creativity setting provides the opportunity to further validate our theory-based process model. If motivating independent individual efforts does not enhance group creativity, then we provide further support for our model suggesting that reward systems better promote group creativity by fostering group cohesion. Ultimately, to the extent that (1) results from individual-creativity settings suggesting that independent efforts do not enhance creativity generalize to a group-creativity setting (Kachelmeier et al. 2008; Kachelmeier and Williamson 2010), and (2) our model suggesting that reward systems spark group creativity by promoting group cohesion is descriptive, we do not expect individual-based tournaments to have a positive effect on group creativity relative to individual piece-rates.

Hypotheses

Based on the preceding discussion, we expect that group tournament pay, but not individual tournament pay, will lead to a more creative group solution than group and individual piece-rate pay, respectively. Accordingly, we predict an ordinal interaction between the level and form of creativity-contingent incentives. For clarity, we use two hypotheses to describe the form of the expected interaction.

H1: Group tournament pay will lead to a more creative group solution than group piece-rate pay.

H2: Individual tournament pay will not lead to a more creative group solution than individual piece-rate pay.

In addition to testing our formal hypotheses, we also examine the underlying processes driving our results. In particular, we provide a test of our process model in Figure 1 by examining whether group cohesion at least partially mediates the positive group creativity effect of group tournament pay. Moreover, we explore how our experimental conditions affect aspects of groups' idea generation, development, and selection processes.

III. METHOD

Participants

We recruited 180 undergraduate student volunteers from upper-level business classes of a large state university to participate in one of 14 75-minute experimental sessions (9 to 18 participants per session). The participants included 17 percent sophomores, 73.5 percent juniors, and 9.5 percent seniors, and 48 percent of the participants were female. We randomly assigned participants to three-person groups and all group interaction occurred via computer. To ensure anonymity, we assigned each participant a code consisting of a group number and one of three letters (A, B, or C).

Experimental Procedures

At the start of each session, participants read through a set of instructions on their computer screen. Appendix A provides the experimental instructions, including a screen shot summarizing the screen functions of the computer program that facilitated group-member interactions. After reading the instructions, individuals practiced using the software. No communication with group members took place during the practice session. We resolved any questions or confusion regarding the software during the practice session.

After the practice session, participants read about their incentive scheme, which was located on the top right corner of their computer screen. As a manipulation check, participants answered a pre-experimental question regarding the incentive scheme immediately after reading the incentive scheme. We checked every participant's answer to confirm that they understood their incentive scheme before we started the idea generation session.

In the idea generation session, each three-person group spent 30 minutes developing a specific proposal for a *creative use* for an abandoned house located on their college campus. Consistent with the psychology literature (e.g., Amabile 1996), the instructions defined a *creative use* as "a use that is original, innovative, and implementable within a reasonable budget." We provided each group with a brief history and a floor plan of the two-story house.

During the 30-minute proposal development phase, group members interacted via a collaborative "ideation program" (Toubia 2006). The ideation program organizes group member inputs in trees where initial thoughts or ideas ("parent-ideas") appear on the far left of the screen and follow-up ideas ("child-ideas") appear to the right of the associated parent-ideas. At any time during the experiment, participants could choose to either contribute a new parent-idea or build on an existing parent or child idea. Each idea was labeled with the identification code of the group member providing the input.

For example, a group member initiated the parent-idea, "Experimental house for energy efficiency." Under this parent-idea, a group member added the following child-idea, "Moreover, part of the project could be addressing how to modernize energy consumption while keeping historical significance intact." While the group developed this proposal, another group member added another parent-idea, "historical museum for children," which was also subsequently developed further with child-ideas.

Participants could also provide comments on any idea in a tree. Group members often used comments to coordinate group efforts. For example, participants used comments such as, "we need to discuss what to put in the [museum]," to focus the group's efforts. Additionally, groups used the comment function for general discussion about the ideas such as one group member commenting, "there are already so many [restaurants] on campus, do you think it would work?" Another group member responded, "that could work because [the house] is on the other side of campus where there aren't many eating places." Each comment was labeled with the identification code of the group member providing it.

After the 30-minute proposal development phase, the experimenter disabled the ideation program. Each group then selected one of the proposals it developed as the group solution. Specifically, each group submitted a parent-idea with all its associated child-ideas as the group's solution. During the idea selection period, group members could communicate only via the comment function and they could not add any new parent- or child-ideas. Each group member had to agree on the specific proposal to submit. To ensure that the group members reached an agreement, the last comment of each group member had to identify the same selected idea. All groups reached consensus.

Panels A and B of Exhibit 1 provide a sample submitted proposal from the group and individual tournament conditions, respectively. Notice that in the proposal from the group tournament pay condition, group members built extensively on each other's parent- and child-ideas. By contrast, in the proposal from the individual tournament condition, the individual initiating the selected idea performed the bulk of the idea development. As illustrated in the "Results" section, these proposals are representative of their respective experimental conditions.

After selecting a proposal, each participant independently completed a post-experimental questionnaire addressing aspects of group cohesion and collecting demographic and other information. Participants received a $5 show-up fee after the session. In addition to this show-up fee, as described below, participants also received performance-contingent compensation approximately four weeks after the experimental session, the nature of which depended on the experimental condition of the group.[4] The experiment involved no deception of any kind.

Experimental Design

We randomly assigned each three-member group to one of four experimental conditions created by manipulating two dimensions of participants' reward system in a between-subjects design. We describe these two factors below.

Level of Creativity-Contingent Incentives

Our first manipulated factor is the level of the creativity-contingent incentive provided to participants. Half of the participant-groups received compensation based on the creativity of their group's solution. The other half received compensation based on the creativity of their individual input to the group's solution.[5]

A panel of three graduate students from the same business school as our participants rated the creativity of proposals. Working independently and blind to our experimental manipulations, each rater read through the same set of instructions as our participants and the submitted solutions of all groups. They then rated the creativity of each group solution on a scale from 0 (lowest creativity) to 10 (highest creativity). We instructed the raters to ensure the average rating across all solutions was a 5.

These raters also evaluated the creativity of each individual group member's input to the group's submitted solution. To facilitate these evaluations, we labeled each input to the solution with the code of the participant who provided the input. Again, raters evaluated the creativity of

---

[4] We informed participants of this delay when recruiting them.

[5] By rewarding participants for their individual contribution to the selected group solution, we attempt to give the individual-based incentive condition its best chance of increasing the creativity of the group solution. That is, since groups would most likely select one of their best ideas as the group solution, participants in the individual reward condition would have an incentive to creatively develop the group's best ideas in order to increase their assigned performance measure. However, we subsequently conducted a supplemental experiment in which we measured and rewarded individuals based on the creativity of their input to all group ideas. Our results are robust to this alternative measure of individual creativity.

EXHIBIT 1

Submitted Group Proposals from the Group and Individual Tournament Pay Conditions

Panel A: Example of a Group Proposal from the Group Tournament Pay Condition

B: Bed & Breakfast

B: More precisely, we would have to hire some personnel to manage the B&B. this may be too costly considering staff, maids, person to do laundry

C: However, people would pay a lot to stay there, especially the elderly

B: On the other hand, would people pay a lot to stay in a run-down place?

C: On the other hand, it's gonna get fixed up

A: Indeed, people may pay more, but what is to say that the iHotel is does not offer more?

B: However, people may pay more for the more quaint experience, so maybe our target would be the elderly

C: More precisely, yes, old people have lots of money. Staying in the oldest building on campus would be more enjoyable than writing a check. Perhaps a contest that allows the winning donors to stay in the house for a weekend?

B: Indeed, having a contest for incentive is a good idea and we can advertise the house as very fixed up and comfortable to make the elderly feel more at home.

C: yep we have to think creativity here

A: Indeed, is keeping the integration of the museum and the bed n breakfast out of the question here?

C: well that is a great idea. Having the b and b themed like a museum for the old people. they would like that

A: In particular, need to discuss how and what to fill the house with artifacts, artwork, displays, holographic theaters, What is the underlying theme of the museum? University over the past 150 years, development of state over that time, or both?

A: Indeed, get school to pull things out of the archives or off the walls of libraries or something to put into it.

C: More precisely, I think we need to drop the robotic holographic talking theater idea. too futuristic, especially for the elderly. The theme of the museum would be the history of the university, with rotating displays

C: so are we leaning toward this for our creative pick. It is getting tricky to follow all of these threads

A: More precisely, I think since we have two creative ideas we should incorporate both. Unless anyone has a better idea. time is kind of limited

C: More precisely, could not agree more

A: Indeed, You could have all types of incentive and sponsoring events depending on the time of year to allow big donors to invite who every the like to stay there for the weekend or you could have large donors for the football stadium stay there at no char

A: Another way to look at this is what if we incorporate the bed n breakfast with the museum idea and have it be decorated with artwork and artifacts from around the state and University. Possible have an interactive room. It would incorporate the two lar

B: Indeed, nice, take two ideas and put it into one. It would be a good idea to decorate it with artwork and artifacts when renovating.

C: should we create a new thread for the combined art museum and b and b idea

(continued on next page)

EXHIBIT 1 (continued)

B: Bed & Breakfast

- **B**: In particular, we would also have to hire cooks to make the breakfast
  - **A**: Instead, Have the mangers who run the house cook like an actual bed n breakfast
    - **B**: On the other hand, i don't think it's a good idea to have managers be the cooks, because then who would manage the place and the staff?
      - **C**: Another way to look at this is a general manager of the property would
- **B**: In particular, how much would we charge the guests? Would this be enough to cover all of the costs? How would we advertise the B&B?
  - **A**: More precisely, is the location of the house in proper city zone for it it be converted into a bed n breakfast for the public's use?
    - **B**: However, I'm sure location is fine considering it is on-campus. It would be ideal for grandparents visiting their grandchildren who attend the University because they would be on-campus
      - **A**: In particular, could we try an move the house to a better or more convenient location?
- **B**: More precisely, so just to make it clear, this B&B would be renovated and decorated with historical artwork and artifacts to provide a comfortable and quaint experience to the elderly.
  - **B**: More precisely, what other details do we need to figure out? We figured out general labor expenses for personnel to maintain the place. We need to get washing and dryer machines to clean linens.
    - **A**: More precisely, I'm sure we could get a majority of this to get donated
  - **B**: In particular, we could also get donations from the university or alumni to support the continued renovation of this historical landmark

Panel B: Example of a Group Proposal from the Individual Tournament Pay Condition

C: A coffee shop

- **C:** More precisely, it could be themed as a university café
- **C:** More precisely, This coffee shop idea would go hand-in-hand with 1799, because if it operated as a cafe, it would be a place for students and faculty to lounge and relax
- **C:** More precisely, It could be themed as University Cafe- and host various significant University memorabilia on the walls/upstairs, while functioning as a cafe where students and faculty could relax. It could also feature a specialty dessert or coffee drink theme
- **A:** One problem with this approach is Moreover, we can also maybe incorporate idea 1814 with the cafe feel.
- **C:** More precisely, To go along with the coffee shop idea, it is something that students and alumni alike could come to- enjoy the ambiance, and see the University memorabilia, the upstairs could feature an University museum paying homage to the school mascot.
- **C:** More precisely, It would be a way to connect students- because not many might consider visiting a museum on a regular basis, however they might consider frequently visiting the Campus Café where they can relax, meet new friends, visit with alumni,
  - **A:** More precisely, it would also create a way for alumni to feel at home. A place that has so much history. Maybe it can even house all of the University sports pictures and etc.
  - **C:** More precisely, I agree, it would be such a great way to connect students to their heritage here at the University. Alumni would also love to come back and visit and gain the nostalgia of reliving the Big 4 basketball memories, the College Bowl Game.

each individual's input on a scale from 0 (lowest creativity) to 10 (highest creativity). We instructed the raters to ensure the average rating across all individual ratings was a 5. Cronbach's alpha for the group and individual ratings was 0.89, indicating a reasonable level of consistency in the ratings. Thus, we averaged the three ratings to obtain our measure of group and individual creativity.[6]

To help validate the graduate student ratings, we also obtained creativity ratings from an expert. Specifically, a manager from the campus historic preservation office that manages the abandoned house ranked six group solutions that we chose to represent the full range of our actual creativity ratings. These rankings corresponded perfectly with the rank order of the average creativity ratings by the graduate students.

Form of Creativity-Contingent Incentives

Our second manipulated factor is the form of the creativity-contingent incentive. We paid half of our participant-groups a linear piece-rate based on their assigned performance measure. The other half of our participants received tournament pay where the participant or group performing best among three competitors received the highest compensation. Here, participants rewarded based on group creativity competed against two other groups in their session (i.e., an intergroup tournament), and participants rewarded based on individual creativity competed against the two other individuals in their group (i.e., an intragroup tournament).

Across all four conditions, we held average creativity-contingent compensation constant at $15 per participant.[7] In our individual piece-rate condition, participants received $3 multiplied by their individual input creativity rating where, as discussed above, the average rating was a 5.[8] In our group piece-rate condition, groups received $9 multiplied by their group creativity rating, where the average rating was a 5, and the three group members equally shared this piece-rate. In our individual (intragroup) tournament condition, the group member with the highest individual input creativity rating of the three group members received $45 and the other two group members received $0. Finally, in the group (intergroup) tournament condition, the group with the highest group creativity rating of the three groups received $135, where the three group members equally shared this tournament pay, and the other two groups received $0.

IV. RESULTS

We now present analyses that investigate the effects of the level (group versus individual) and form (piece-rate versus tournament) of the creativity-contingent incentive on the creativity of the group solution and the underlying processes driving these effects. We conduct all analyses at the three-person group level. As such, we average the individual scores of each group's three members when applicable. For our hypotheses tests and supplemental analyses, we control for the percentage of females in each group, calculated by dividing the number of female group members by 3. We do so because prior research suggests that females both tend to participate more in computer-mediated discussions (Hsi and Hoadley 1997) and ultimately tend to be more creative on discussion-based tasks (Picariello 1994).[9] Therefore, as discussed in Kinney (1986), we use the percentage of females in each group as a covariate to increase the power of our statistical tests by removing variance that is unrelated to our research question of interest.[10]

---

[6] We asked the creativity raters to provide a justification for each of their ratings. Based on these justifications, proposals receiving a high creativity rating often developed either an original/innovative overall theme that was implementable or an ordinary overall theme with original/innovative aspects such as creative ways to interface with student groups on campus. Examples of creative proposals include: (1) a Civil War Visitors Center serving food and presenting theater/other entertainment consistent with the time period, giving a creative outlet to student groups across campus, and (2) allowing student groups from each college to turn a room into an exhibit in order to introduce prospective students to each college's offering, where, in each year, student groups with the best exhibit receive funding for their organizations. Proposals receiving lower creativity ratings typically developed a use associated with a college campus without original/innovative aspects such as (1) a coffee shop, or (2) a space that can be rented out by groups on campus.

[7] Participants received an average compensation of $20 (i.e., $5 show-up fee + $15 average creativity-contingent compensation). They also received extra credit from the courses in which we recruited them for participating in the experiment.

[8] We communicated the creativity rating range and average in participant instructions.

Test of Hypotheses—Creativity Ratings

Our hypotheses predict an ordinal interaction such that group tournament pay will lead to a more creative group solution than group piece-rate pay (H1) and individual tournament pay will not lead to a more creative group solution than individual piece-rate pay (H2). Panel A of Table 1 provides descriptive statistics for group creativity ratings. With group creativity ratings as our dependent measure, Panel B of Table 1 provides the results of an ANCOVA with form and level of incentives as our independent variables.[11] Consistent with our hypotheses, this ANCOVA yields a significant form × level interaction ($F = 12.30$, one-tailed $p = 0.04$).

Follow-up analyses on this interaction, reported in Panel C of Table 1, provide formal tests for our hypotheses. Consistent with H1, participants with group tournament pay developed more creative group solutions than those with group piece-rate pay ($F = 2.34$; one-tailed $p = 0.06$). Consistent with H2, participants with individual tournament pay did not develop more creative group solutions than those with individual piece-rate pay ($F = 1.18$; two-tailed $p = 0.28$). Moreover, while not statistically significant at conventional levels, average group creativity ratings drop from 5.47 for participants with individual piece-rate pay to 4.87 for participants with individual tournament pay, suggesting that, if anything, individual tournament pay is detrimental to group creativity. Collectively, these results fully support our hypotheses.[12]

Test of Process Model

Development of our first hypothesis argues that group tournaments lead to more creative group solutions than group piece-rates by promoting greater group cohesion. Group cohesion encapsulates beliefs about the psychological bond among group members, the openness of group members to the ideas of others, and the extent to which members are united in trying to achieve the group objective. We capture judgments about group cohesion using eight post-experimental questions adapted from the Group Environment Questionnaire (GEQ) scale (Widmeyer et al. 1985). Panel A of Table 2

---

[9] Consistent with this reasoning, females contributed more words during the group discussion than males ($t = 1.87$; one-tailed $p = 0.03$) and our percentage of female covariate is positively related with group creativity ($F = 14.14$; $p < 0.01$). This covariate is significant in most analyses. However, for expositional convenience, we only report the statistic on this covariate for tabulated results.

[10] Other demographic information we collected such as the percentage of native English speakers and the average age of the group is not significantly related to group creativity and, therefore, we do not include these variables as covariates in our analyses.

[11] Given the same three individuals provided creativity ratings for all groups and individuals, we include creativity rater as a within-subjects factor when analyzing both group and individual creativity ratings. We find neither a main effect of creativity rater nor any significant creativity rater by between-subjects factor interactions (all p's $>$ 0.50). Thus, we neither tabulate nor report these results.

[12] After removing the effects of the percentage of females in the group covariate, adjusted group creativity means by condition are as follows: 5.86 for the group tournament, 5.41 for the group piece-rate, 5.09 for the individual piece-rate, and 4.87 for the individual tournament. Without the covariate, our form × level interaction is still significant ($F = 12.30$; one-tailed $p = 0.04$). Moreover, we find group tournaments increase group creativity ($F = 1.87$; one-tailed $p = 0.086$) and individual tournaments have no effect on group creativity ($F = 1.33$; two-tailed $p = 0.250$) relative to group and individual piece-rates, respectively. Though slightly weaker, these results do not materially change our inferences.

TABLE 1

The Effects of Level and Form of Creativity-Contingent Incentives on Group Creativity Ratings

Panel A: Means (Standard Deviations) for Group Creativity Ratings[a]

	Individual-Based Incentive	Group-Based Incentive
Piece-Rate Incentive	5.47 (2.67) (n = 15)	5.09 (2.52) (n = 15)
Tournament Incentive	4.87 (2.53) (n = 15)	5.80 (1.91) (n = 15)

Panel B: Analysis of Variance

Factor	df	Mean Square	F	p-value[b]
Form of Incentives[c]	1	0.55	0.29	0.64
Level of Incentives[d]	1	4.98	2.76	0.24
Form × Level of Incentives	1	19.34	12.30	**0.04**
Percent of Female Group Members	1	79.73	14.14	<0.01
Error	167	5.64		

Panel C: Simple Effects

	df	F	p-value[b]
Effect of Incentive Form *within* Group-Level Incentives	1	2.34	**0.06**
Effect of Incentive Form *within* Individual-Level Incentives	1	1.18	0.28

---

[a] An independent panel of three raters assessed the creativity of group solutions.

[b] Reported p-values are two-tailed unless testing a one-tailed prediction, as indicated in bold.

[c] We manipulated *Form of Incentives* between subjects at two levels. Participants received either linear piece-rate pay or participated in a winner-take-all tournament.

[d] We manipulated *Level of Incentives* between subjects at two levels. Participants received pay based on either the creativity of the group solution (Group-Based Incentive) or the creativity of their individual input to the group solution (Individual-Based Incentive).

summarizes the specific statements used to capture group cohesion and the descriptive statistics by condition for participants' responses to eight 11-point Likert scale statements with "0" labeled "not at all" and "10" labeled "completely." As reported in Panel B of Table 2, factor analysis of individual responses indicates that all eight items load on one factor (all loadings > 0.50). Moreover, the Cronbach's alpha on these eight measures is 0.87, which exceeds typical reliability thresholds (Peterson 1994). Accordingly, we base the analyses in this section on the average of all eight items.

Untabulated results suggest that, consistent with our theoretical model, group tournament pay increases group cohesion relative to group piece-rate pay ($F = 2.88$; $p = 0.05$, one-tailed), and that individual tournament pay has no effect on group cohesion relative to individual piece-rate pay ($F = 0.02$; $p > 0.50$, two-tailed). Collectively, these results suggest that group tournament pay, but not

Descriptive Statistics and Factor Analysis of Group Cohesion Measure

Panel A: Descriptive Statistics of Statements Used to Capture Group Cohesion

	Group-Based Incentive Mean (Standard Deviation)		Individual-Based Incentive Mean (Standard Deviation)	
Statement	**Piece-Rate**	**Tournament**	**Piece-Rate**	**Tournament**
1 As a whole, I liked the members in my group.	7.51 (8.13)	8.13 (1.78)	7.02 (2.15)	7.04 (2.04)
2 Our group was united in trying to generate a creative idea.	7.73 (2.44)	8.69 (1.41)	7.13 (2.79)	7.16 (2.36)
3 My group did not give me enough opportunities to contribute my ideas. (Reverse Coded)	8.93 (1.78)	8.91 (1.82)	8.24 (2.16)	8.07 (2.40)
4 I did not like the style of work in this group. (Reverse Coded)	6.87 (3.01)	7.87 (2.28)	7.07 (2.05)	7.27 (2.28)
5 I felt attached to the group.	5.24 (3.18)	5.58 (2.79)	4.33 (3.19)	4.64 (2.99)
6 I felt quite similar to others in my group in terms of general attitudes and opinions.	6.64 (1.98)	7.60 (1.44)	6.13 (2.12)	6.11 (1.91)
7 I think my group was relatively more cohesive (united) compared to other groups in this study.	6.33 (2.42)	7.27 (1.53)	5.58 (2.20)	5.67 (2.33)
8 My group members were open to the ideas of others.	7.89 (1.80)	8.02 (1.99)	7.51 (2.83)	7.27 (2.21)
Average	7.14	7.76	6.63	6.65

Adapted from the Group Environment Questionnaire (Widmeyer et al. 1985).

Panel A of this table summarizes the statements used to capture group cohesion and the descriptive statistics of participant responses to these statements by condition. We elicited each statement using an 11-point Likert scale with "0" labeled "not at all" and "10" labeled "completely." We averaged responses across each group such that n = 15 for each condition.

Panel B of this table presents factor analysis for participants' responses to each statement.

individual tournament pay, enhances group cohesion relative to group and individual piece-rates, respectively.

We further investigate whether group cohesion partially mediates the positive group creativity effect of our creativity-contingent incentive conditions. We establish partial mediation if the following three conditions are met: (1) group tournament pay significantly increases group creativity as we demonstrate in Panel C of Table 1, (2) group tournament pay significantly increases group cohesion as we demonstrate in the paragraph above, and (3) controlling for the group creativity effect of group tournament pay, group cohesion still significantly increases group creativity (Baron and Kenny 1986; MacKinnon et al. 2002).[13,14] To test this final condition, we re-estimate the ANCOVA and follow-up analyses summarized in Table 1 after adding our measure of group cohesion as a covariate.[15] Consistent with condition (3), untabulated results show that group cohesion is still significantly associated with group creativity after controlling for group tournament pay ($F = 4.38$; one-tailed $p = 0.02$). Collectively, these analyses are consistent with group cohesion partially mediating the positive group creativity effect of group tournament pay.[16]

Did Group Tournament Pay Affect Idea Generation and\or Idea Development?

Given that group tournament pay enhances cohesion and ultimately leads to more creative group solutions relative to group piece-rate pay, it is also useful to explore whether groups in this condition went about forming their solution in discernibly different ways. In particular, groups across organizations differ in the extent that they are responsible for some or all aspects of the creative process such as generating an initial set of ideas and developing these ideas (West et al. 2006). While some groups such as those in our experiment are responsible for both generating and developing ideas, others are merely responsible for one piece of the creative process such as brainstorming an initial undeveloped set of potential problem solutions. As such, exploring where in the creative process group tournament pay influences behavior may provide a better understanding of whether group tournament pay can promote more creative group solutions across groups with these varying levels of responsibilities. That said, while theory suggests that participants in the group tournament condition exhibit greater tendencies to share ideas and build on each other's ideas, it is not clear *a priori* precisely how these tendencies systematically affect groups' solution-formation processes. Thus, we explore whether and, if so, how these tendencies materialize in the generation of initial ideas and the development of these initial ideas.

First, we examine whether group tournament pay increases either the number or diversity of initial ideas considered. To examine the number of ideas considered, we simply count the number of parent (initial) ideas generated by each group. Untabulated results highlight that group

---

[13] See also David A. Kenny's mediation website for a very helpful discussion (http://davidakenny.net/cm/mediate.htm).

[14] Similarly, the joint significance test argues that if the effect of group tournament pay is significantly related to group cohesion (α) and group cohesion is significantly related to group creativity after controlling for group tournament pay (β) as we demonstrate in steps 2 and 3, then the indirect (mediating) effect captured by $\alpha \times \beta$ is also significant. MacKinnon et al. (2002) compares different methods to test mediation and concludes that the joint significance test provides the best balance of Type I error and statistical power.

[15] That is, with group creativity rating as our dependent measure, we estimate an ANCOVA with form of incentives (piece-rate versus tournament pay) and level of incentives (individual-based versus group-based) as our independent measures, as well as the percentage of females in each group and group cohesion as covariates.

[16] If group cohesion were to fully mediate the relation between our reward conditions and group creativity, we would no longer observe a significant group creativity effect of our reward conditions after controlling for group cohesion (Baron and Kenny 1986; MacKinnon et al. 2002). However, after controlling for cohesion, our level × form interaction continues to be significant ($F = 10.10$; one-tailed $p = 0.04$). Thus, although the significance of the follow-up comparison between group tournament and group piece-rate is reduced ($F = 1.59$; one-tailed $p = 0.105$), our results suggest that group cohesion partially, rather than fully, mediates this relation.

tournament pay did not affect the number of parent-ideas generated relative to group piece-rate pay (7.93 versus 8.80 average parent-ideas; $F = 0.53$; two-tailed $p = 0.47$). Second, we examine the diversity of these initial ideas by having a research assistant who was blind to the study's hypotheses categorize all parent-ideas into common categories or themes. This exercise generated ten categories, of which the two most common were "history, museum, and gallery" and "academic support services."[17] We then counted the number of distinct categories included in each group's set of initial ideas. Again, untabulated results demonstrate that group tournament pay did not affect the number of distinct parent-idea categories considered relative to the number generated under group piece-rate pay (5.93 versus 5.87 average categories; $F < 0.01$; two-tailed $p > 0.50$). Collectively, these results suggest that group tournament pay affected neither the number nor the diversity of initial ideas generated relative to group piece-rate pay.[18]

Second, we examine whether group tournament pay increases the extent to which group members build on each others' ideas when developing initial ideas. To capture this aspect, we examine the depth of idea development. We measure this construct as the maximum number of layers of ideas and comments contained in a parent-idea. For example, a parent-idea with two child-ideas both building on the parent-idea has a depth of 2, whereas a second parent-idea with two child-ideas, the first building on the parent-idea and the second building on the first child-idea, has a depth of 3.[19] We interpret the latter structure of idea development as reflecting a higher degree of collaboration among group members and greater extent of elaboration on a particular idea. Untabulated results suggest that group tournament pay leads to greater idea depth relative to group piece-rate pay (12.00 versus 7.87 average depth; $F = 3.51$; one-tailed $p = 0.03$).[20,21] Collectively, while participants with group tournament pay did not consider a greater number/diversity of initial ideas, they did build off each others' thoughts to a greater extent when developing these initial ideas.[22]

Did Reward Systems Affect Propensities to Select the Most Creative Idea?

The creativity of a group solution is a joint function of idea generation/development and idea selection. Because group members must ultimately select one of their ideas to submit, idea selection could affect the group's creativity rating. The magnitude of verbiage in our group interaction transcripts makes any meaningful evaluation of unsubmitted thoughts and proposals difficult. However, to explore the effect of our experimental conditions on potential variations in idea selection, we had a graduate student from the participants' university (not one of our original creativity raters) read the transcript of each group's interaction during the 30-minute proposal development phase. This rater then selected and ranked the three most creative solutions of each group without knowing which idea the group actually selected. We compare the idea our rater identified as most creative with the idea actually selected by each group.

---

[17] The ten categories from most to least common include: (1) history, museum, and gallery; (2) academic support services; (3) dining and drinks; (4) hotel and related; (5) outreach services; (6) student lounge; (7) entertainment; (8) community related (e.g., church, community center); (9) store; and (10) experimental house for energy efficiency.

[18] Comparing across the individual tournament and piece-rate conditions, we observed differences for neither the number (7.93 versus 6.67 average parent-ideas; $F = 0.75$; two-tailed $p = 0.39$) nor diversity ($F < 0.01$; two-tailed $p > 0.50$) of ideas considered by the group. Also, when comparing across our group and individual reward conditions, we do not observe significant differences for either the number of parent-ideas ($F = 0.95$; $p = 0.33$) or the number of distinct categories of parent-ideas ($F = 1.07$; $p = 0.31$).

[19] For this measure, a comment immediately following (building on) another comment also increases depth.

[20] Additionally, we find that our group cohesion measure is positively correlated with idea depth ($\rho = 0.22$; $p = 0.04$).

[21] Individual tournament pay did not lead to greater idea depth relative to individual piece-rate pay (5.67 versus 5.47 depth; $F = 0.01$; two-tailed $p > 0.50$).

[22] This result suggests that group tournament pay is more likely to increase the creativity of group solutions relative to group piece-rate pay for groups responsible for the idea-development aspect of the creative process. However, future research that investigates the efficacy of group tournament pay across groups with varying responsibilities for aspects of the creative process is needed to further validate this conclusion.

Across the 15 groups in each of our four conditions, the idea our rater identified as most creative was actually selected by the group 11 times in the group tournament, eight times in the group piece-rate, eight times in the individual tournament, and seven times in the individual piece-rate conditions. These relative proportions did not statistically differ across our four conditions ($\chi^2 = 2.43$; $p = 0.49$). Moreover, one of the two most creative ideas identified by our rater was selected by the group 13 times in the group tournament, 11 times in the group piece-rate, 12 times in the individual tournament, and 12 times in the individual piece-rate conditions. Again, these relative proportions did not differ across conditions ($\chi^2 = 0.83$; $p > 0.50$). Overall, we did not observe differences across our experimental conditions in groups' propensities to select the most creative ideas, suggesting that idea selection is unlikely to have affected our primary results.

Effects of Individual-Based Creativity-Contingent Incentives

We conclude our discussion of results by examining the implications of rewarding participants for the creativity of individual inputs. As already discussed, rewarding the creativity of individual inputs does not enhance group creativity irrespective of the incentive's form. Furthermore, consistent with our theoretical development, rewarding individual creativity also does not enhance individual creativity irrespective of the incentive's form. Panel A of Table 3 provides descriptive statistics for creativity ratings of individual inputs. With these individual creativity ratings as the dependent measure, Panel B of Table 3 provides the results of an ANCOVA with form and level of incentives as our independent variables. We find a significant main effect of the level of incentives suggesting that individual-based incentives decreased the creativity of individual inputs relative to group-based incentives ($F = 10.41$; two-tailed $p = 0.08$). This main effect is qualified by a significant form × level interaction ($F = 24.08$, one-tailed $p = 0.02$).

Follow-up analyses reported in Panel C of Table 3 shows that group tournament pay leads to more creative individual inputs relative to group piece-rate pay ($F = 5.11$; one-tailed $p = 0.01$).[23] This result is consistent with our theoretical development suggesting that group tournament pay increases the creativity of individual input by encouraging participants to synthesize and build on the many perspectives of group members. We did not observe an effect of tournament pay on individual creativity across our individual-based incentive conditions ($F = 0.14$; two-tailed $p = 0.71$).

While individual-based creativity-contingent incentives did not increase creativity, they did motivate greater independent individual effort. We assess independent individual efforts by assessing group members' energy devoted to developing their own ideas. Specifically, we count the number of words contained in parent-ideas (i.e., initial ideas) and the number of words in child-ideas that build on group members' *own* ideas. Untabulated results suggest that individual-based incentives did increase individual efforts relative to group based incentives (431.54 versus 309.07 words developing own ideas; $F = 9.26$; $p < 0.01$). Further, our theoretical development suggests that individual tournament pay would increase individual efforts relative to individual piece-rate pay. While the pattern of means is in the expected direction (443.47 versus 419.60 words developing own ideas), this

---

[23] To ensure that low creativity scores of individuals who did not contribute to the selected group idea are not driving our results, we replicated our results using the maximum individual creativity rating for each group. Using this measure does not change the inferences we make.

TABLE 3

The Effects of Level and Form of Creativity-Contingent Incentives on Individual Creativity Ratings

Panel A: Means (Standard Deviations) for Individual Creativity Ratings[a]

	Individual-Based Incentive	Group-Based Incentive
Piece-Rate Incentive	5.22 (2.48) (n = 15)	4.89 (2.28) (n = 15)
Tournament Incentive	5.00 (2.40) (n = 15)	5.89 (1.71) (n = 15)

Panel B: Analysis of Variance

Factor	df	Mean Square	F	p-value[b]
Form of Incentives[c]	1	8.56	5.67	0.14
Level of Incentives[d]	1	4.98	10.41	0.08
Form × Level of Incentives	1	16.60	24.08	**0.02**
Percent of Female Group Members	1	69.31	14.46	<0.01
Error	167	4.79		

Panel C: Simple Effects

	df	F	p-value[b]
Effect of Incentive Form *within* Group-Level Incentives	1	5.11	**0.01**
Effect of Incentive Form *within* Individual-Level Incentives	1	0.14	0.71

[a] An independent panel of three raters assessed individual creativity. We averaged responses across each group such that n = 15 for each condition.

[b] Reported p-values are two-tailed unless testing a one-tailed prediction, as indicated in bold.

[c] We manipulated *Form of Incentives* between subjects at two levels. Participants received either linear piece-rate pay or participated in a winner-take-all tournament.

[d] We manipulated *Level of Incentives* between subjects at two levels. Participants received pay based on either the creativity of the group solution (Group-Based Incentive) or the creativity of their individual input to the group solution (Individual-Based Incentive).

difference is not significant ($F = 0.20$; one-tailed $p = 0.33$).[24] Nevertheless, the fact that this measure is higher in the individual tournament condition relative to the average of this measure across the other three conditions provides some limited evidence that individual tournament pay tends to promote independent individual efforts ($F = 4.87$, one-tailed $p = 0.02$).

While this latter result is admittedly only suggestive, it is relevant to the objective of examining individual-based creativity-contingent incentives. Specifically, we desire to investigate whether findings from prior management accounting research, suggesting that motivating individual efforts does not lead to more creative output, generalize to a group setting. Consistent with this argument, neither individual nor group creativity ratings increase in our individual tournament condition relative to our other conditions. Moreover, these creativity ratings did not increase in our individual-based conditions relative to our group conditions. Collectively, our results suggest that motivating independent individual efforts does not appear to enhance individual or group creativity.[25]

---

[24] Group tournament pay also did not increase individual efforts relative to group piece-rate pay (278.27 versus 330.87 words; $F = 1.54$; two-tailed $p = 0.22$).

Supplemental Experiment

A potential concern is that our finding that individual tournament pay does not enhance creativity relative to individual piece-rate pay could be driven by how we measured and rewarded individual creativity in our original experiment. Specifically, while we chose to measure the creativity of individual input to only the selected group solution in order to encourage individuals to develop the group's best ideas, the resulting individual tournament scheme could be demotivating. For example, to the extent that individuals under the individual tournament scheme believed that the group member who offered the initial parent-idea of the selected solution would win the intragroup tournament, such individuals may have had very limited incentive to creatively develop the group's best or any other idea.

Therefore, we conducted a supplemental experiment replicating our two individual-based incentive treatments using a different performance measure, the creativity of each group member's input to the entire group discussion. Specifically, in the supplemental experiment, the participants were told that "each group member will receive a single rating based on the creativity of his/her input to both the group's selected idea and any ideas not selected by the group." With this one exception, we used the same set of instructions and experimental material as in our original experiment.[26]

Table 4 reports descriptive statistics of the resulting creativity ratings. Not only does the pattern of means suggest that individual tournament pay is detrimental to group creativity relative to individual piece-rate pay, as in our original experiment, but also this decrease is statistically significant ($t = 2.72$; two-tailed $p < 0.01$). Moreover, as in our original experiment, the form of the individual reward did not affect individual creativity ($t = 1.22$; two-tailed $p = 0.23$). Collectively, results from our initial experiment suggesting that individual tournament pay does not increase creativity relative to individual piece-rate pay are robust to this alternative way of measuring and rewarding the creativity of individual input.

V. CONCLUSIONS

We report the results of an experiment where three-person groups develop a creative solution to an important problem via computer interaction. In this environment, we examine whether the efficacy of either individual- or group-based creativity-contingent incentives depends on whether the incentives take the form of a piece-rate or tournament. Consistent with our theory-based process model, we find that intergroup tournament pay increases group cohesion and ultimately leads to more creative group solutions relative to group piece-rate. We further illustrate that group tournament pay increases the extent to which group members build on each others' ideas relative to group piece-rate pay. Further validating our model, we find that, while intragroup tournament pay increases individual efforts relative to the average of the other conditions, it does not enhance the creativity of group solutions or individual inputs to group solutions.

---

[25] Consistent with this argument, our measure of individual effort is correlated with neither individual nor group creativity ratings (both p's > 0.42)

[26] We recruited an additional 90 undergraduate student volunteers from upper-level business classes of the same university as our initial experiment. As such, identical to our original experiment, 15 three-person groups per condition participated in our supplemental experiment.

TABLE 4

Creativity Ratings in a Supplemental Experiment[a]

	Piece-Rate Incentive[b]	Tournament Incentive[c]	t-statistic	Two-Tailed p-value
Creativity Rating of Group's Submitted Solution[d]	5.69 (1.25) (n = 15)	4.67 (0.74) (n = 15)	2.72	0.01
Creativity Rating of Individual Input to All Group Ideas	5.46 (1.02) (n = 15)	5.00 (1.05) (n = 15)	1.22	0.23

---

[a] This table summarizes creativity ratings for a supplemental experiment we conducted to replicate our two individual-based incentive treatments using a different performance measure, the creativity of individual input to all group ideas. With this one exception, we used the same set of instructions and experimental material as in our original experiment (see Appendix A).

[b] Participants in the Piece-Rate Incentive condition received a linear piece-rate based on the creativity of their individual input to all group ideas.

[c] Participants in the Tournament Incentive condition received tournament pay where the participant who received the highest creativity rating, out of three competitors, for his/her individual input to all group ideas, received the highest compensation while the two other competing participants received nothing.

[d] Both the creativity of group's submitted solution and the creativity of individual input to all group ideas were assessed by an independent panel of three raters.

Our results contribute to a better understanding of observations from practice suggesting that organizations desiring group creativity often induce intergroup competition. For example, innovative companies such as Johnson & Johnson and Procter & Gamble invest heavily in competitive budgeting systems, rewarding members of the most innovative project teams with greater funding and pay (Simons 2000; Nussbaum 2005). Our findings also contribute to a better understanding of academic practices in that research teams and universities are becoming increasingly reliant on competitive grants for the funding of innovative projects (Geuna 2001). Beyond formal organizational practices, our results also provide potential insight with respect to the recent trend of "crowdsourcing." Here, organizations make open calls to groups of people requesting creative solutions to important problems and often pay groups with the most innovative solution. For example, InnoCentive, launched with funding from Eli Lilly, provides a platform where companies such as Boeing and DuPont post pressing R&D challenges to the scientific community and provide financial rewards to teams with the best solutions (Brabham 2008).

More generally, our results highlight the importance of gaining a better understanding of linkages between performance evaluation and reward system design and creativity in group settings. Our existing knowledge of these linkages comes predominantly from individual settings where research often suggests creativity is invariant to reward system design. Consistent with this literature, our results suggest that simply encouraging individual group members to independently work harder at being creative may not lead to the desired result. However, our results suggest that performance evaluation and reward systems can play a vital role in promoting group creativity by encouraging individuals to collaborate and build on the diverse ideas of others. These promising results will hopefully encourage future research in the area.

Limitations of our study provide opportunities for future research. First, we examined a setting in which groups interact for only a single period. Whereas this design choice is representative of some environments, such as the reliance on cross-functional teams formed to creatively address a specific problem, it may not be representative of other environments in which longstanding departments or teams must creatively address on-going problems and, thus, may already be a cohesive and collaborative unit. Second, since we measured cohesion before revealing groups' creativity ratings and compensation in order to help explain behaviors during our experiment, our results do not necessarily speak to feelings experienced after revealing tournament winners. An interesting question for future research is whether groups that ultimately lose an intergroup tournament in a given period continue to both feel highly cohesive and exert collaborative effort. Groups that lose a group tournament may feel discouraged and less cohesive, which could lead to less collaborative effort in future tournaments. Alternatively, groups losing a tournament in a given period may become even more cohesive and determined to win future tournaments, which could promote even more collaborative effort in the future. As such, future research could address the moderating role of multiple-period tournaments on the link between incentive system design, cohesion, and group creativity.

APPENDIX A

EXPERIMENTAL INSTRUCTIONS

Ground Rules

Before describing the experiment, it is important to establish two ground rules.

1. NO TALKING WITHIN OR COMMUNICATION BETWEEN SESSIONS

While we hope that you find this experiment to be fun, it is also serious research. Please help us maintain control over the experiment by refraining from verbal communication with your fellow participants in this session or any communication with other students who might be participating in future sessions. If you have any questions at any time during today's session, just raise your hand and we will assist you.

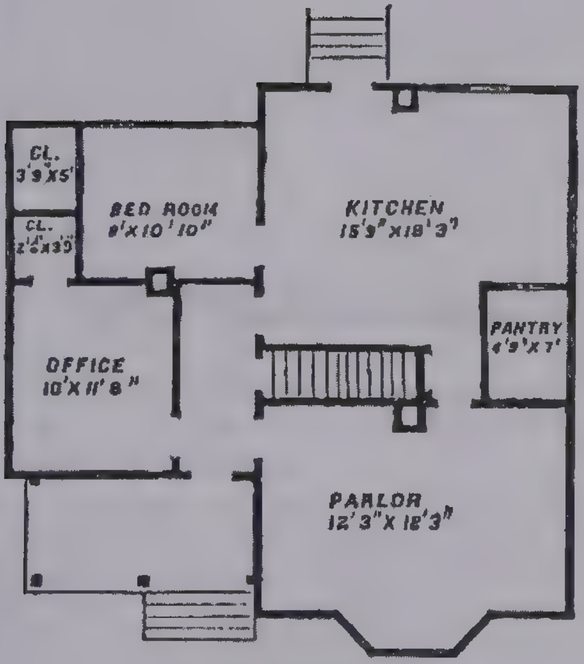
2. NO DECEPTION

We promise to carry out the experiment in the manner described in these instructions, with no deception of any form. You have already received a $5 show-up fee. As will be explained later, you can earn additional compensation from this experiment, which will be paid at a later date (in about four weeks). We promise that your compensation will be determined exactly as described in the rules explained later for this session.

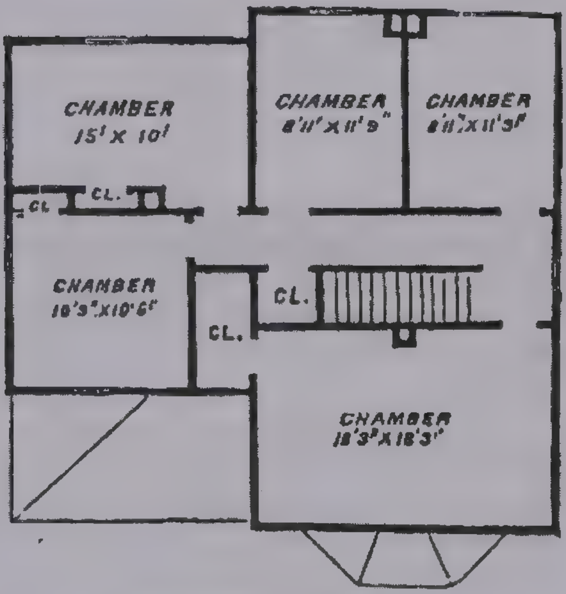
Experimental Task

Participants in today's session have been randomly assigned into groups of three persons each. Each three-person group will spend 30 minutes developing specific proposals for a creative use for the Mumford house located in the South Quad (i.e., a use that is original, innovative, and implementable within a reasonable budget).

Built just after the Civil War in 1870, the Mumford House is the oldest building on our campus. Despite being listed on the National Register of Historic Places, the building has been poorly maintained and, as a result, is currently uninhabited. In order to renew interest in this historical landmark, groups from around the state want to develop a creative use for the building which will help secure money for its renovation.



FIRST FLOOR.



SECOND FLOOR.

Developing Creative Proposals for the Mumford House

For 30 minutes, each group will interact and develop their creative proposals electronically via an ideation program. The ideation program organizes group ideas in "trees" where the original ideas, "parent-ideas," are placed far left of the screen and the follow-up ideas, "child-ideas," are placed below the existing parent-ideas that the child-idea relates. Here is what the ideation program looks like:

(clicking on any word of any statement will refresh this portion of the page - clicking on an idea number will hide/show the ideas that are below it)

-***(idea #77)*** *G1A*: This is a parent-idea.
  -***(idea #78)*** *G1A*: More precisely, This is a child-idea built upon the parent-idea #77.
  comments: *G1A:* This is a comment on the child-idea #78.--

-***(idea #79)*** *G1A*: This is another parent-idea.

TOPIC: Proposals for a creative use for the Mumford house

View the rules of the Game

Your compensation will be determined as follows:
After today's session, experts will rate the creativity of each group's submitted idea on a scale of 0 to 10, where "10" indicates the highest rating, "0" indicates the lowest possible rating, and "5" will be the average rating across all sessions. Each group will be paid $9 multiplied by the group creativity rating. The group payment will be evenly divided among the three group members.

You have 2 options
1. Enter an idea not building on any previous idea

2. Build/comment on an existing idea
Please start by entering the idea number (just the digits, for example 605 for idea #605) and click submit.
submit

Your upper right screen shows how your compensation will be determined.

You can contribute a parent-idea by clicking on "Enter an idea not building on any previous idea".

Your left screen shows ideas and comments that have been generated.

You need to either press "F5" or click on any existing idea to refresh the screen.

You can contribute a child-idea or comment on an existing idea by first selecting the idea number of the existing idea you wish to build on, then clicking submit to enter your idea/comment.

Please note that comments are not considered part of an idea.

Each group's idea-trees are recorded on the left-hand side of the screen. As seen in the image above, all child-ideas that build on a specific parent-idea have the same color and the same indentation.

At any time during the 30-minute interactive group session, group members can choose to either contribute a new parent-idea or build/comment upon an existing parent-idea by clicking on either "Enter an idea not building on any previous idea" or "Enter an idea to react to or build on idea #" on the right-hand side of the screen. When building on ideas, you should generally use "conjunctive phrases" like "More precisely," "In particular." These conjunctive phrases make sure that the ideas in a tree are linked not only verbally, but also conceptually.

> **Note:** New ideas and comments won't appear automatically on the screen. To see new ideas, you have to refresh the page, either by pressing F5 or clicking on any previous idea.

Each group will only be able to observe the ideas and comments of its three members (i.e., not the ideas and comments of participants in other groups).

Submitting a Creative Proposal for the Mumford House

After the 30-minute interactive session, each group will have 5 minutes to select one idea from the idea(s) it developed. Specifically, each group will submit the number of the parent-idea where the discussion and development of its most creative idea began. **Recall:** Parent-ideas are the initial ideas at the far left of the screen.

During this 5-minute period, group members will only be able to communicate via the comment function (i.e., no new parent- or child-ideas can be added).

Remember, comments won't appear automatically on the screen. To see new comments, you have to refresh the page, either by pressing F5 or clicking on any previous comment.

The final comment of the group should indicate the number of the parent-idea selected.

YOUR COMPENSATION

Group Piece-Rate

After today's session, doctoral students will rate the creativity of each group's submitted idea on a scale of 0 to 10, where "10" indicates the highest rating, "0" indicates the lowest possible rating, and "5" will be the average rating across all sessions. Each group will be paid $9 multiplied by the group creativity rating. The group payment will be evenly divided among the three group members.

Group Tournament

After today's session, doctoral students will rate the creativity of each group's submitted idea on a scale of 0 to 10, where "10" indicates the highest rating, "0" indicates the lowest possible rating, and "5" will be the average rating across all sessions. The group receiving the highest group creativity rating out of the three groups in today's session on your side of the lab will receive $135 and the other two groups with receive $0. The group payment will be evenly divided among the three group members.

Individual Piece-Rate

After today's session, doctoral students will rate the creativity of each group member's input to the group's submitted idea on a scale of 0 to 10, where "10" indicates the highest rating, "0" indicates the lowest possible rating, and "5" will be the average rating across all sessions. Each individual will receive $3 multiplied by his/her individual rating.

Individual Tournament

After today's session, doctoral students will rate the creativity of each group member's input to the group's submitted idea on a scale of 0 to 10, where "10" indicates the highest rating, "0" indicates the lowest possible rating, and "5" will be the average rating across all sessions. The individual from each group with the highest rating will receive $45 and the other two individuals will receive $0.

All Conditions

We will pay you your compensation in about four weeks, after we receive the creativity ratings. We promise that you and all others with this version of the research will receive cash compensation as described above for participating today.

Sticks and Carrots: The Effect of Contract Frame on Effort in Incomplete Contracts

Margaret H. Christ

Karen L. Sedatole
Michigan State University

Kristy L. Towry
Emory University

ABSTRACT: In this study, we examine the effect of incentive contract framing on agent effort in an incomplete contract setting. Prior research suggests that when governed by complete incentive contracts, agents exert greater effort under penalty contracts relative to bonus contracts. However, in an incomplete contract setting, in which the incentive contract does not govern all tasks for which the agent is responsible, the agent's trust in the principal is relevant. In this setting, we predict that bonus contracts create a more trusting environment, and this effect spills over to tasks not governed by the incentive contract, such that bonus contracts elicit greater effort on these tasks as compared to penalty contracts. We develop and experimentally validate a theoretical model of the effects of contract frame on trust and effort in this incomplete contract setting. The main intuition behind the model is that the framing of an incentive contract affects the degree to which the contract terms are interpreted by the agent as a signal of mistrust. More specifically, penalty contracts engender greater distrust than do bonus contracts and, therefore, when contracts are incomplete, penalty contracts lead to lower effort on tasks not governed by the contract than do bonus contracts.

I. INTRODUCTION

Incentive contracts are ubiquitous as a means of motivating agent effort and improving firm performance. An incentive contract can be framed as either a bonus that offers an agent a monetary reward if performance goals are met, or as a penalty that reduces monetary payouts if performance goals are not met. Historically, bonus contracts have been more common in practice than penalty contracts.[1] Accounting research provides initial insights into agent *preferences* for bonus contracts (i.e., positively framed contracts) relative to penalty contracts (i.e., negatively framed contracts). Luft (1994) finds that agents prefer bonus contracts to economically equivalent penalty contracts. A potential explanation for this preference is loss aversion (Kahneman and Tversky 1979), the notion that the disutility experienced from a loss is greater than the utility experienced from a gain of the same magnitude. While agent preferences for bonus contracts are consistent with the predominance of bonus contracts observed in practice, principals choose incentive contracts based not solely on the preferences of agents, but rather on the efficiency with which various contracts induce desired agent effort levels.

While a large literature in psychology, economics, and accounting examines the effort-inducing effects of bonus contracts, few studies examine the effort-inducing effects of penalty contracts. One exception is Hannan et al. (2005), who find that despite stated preferences for bonuses, agents exert greater effort under penalty contracts so they can avoid paying the penalty. Hossain and List (2012) similarly find field evidence of greater effort under a penalty contract relative to a bonus contract. Authors of both studies conclude that the same loss aversion that induces a preference for bonus contracts induces higher effort under penalty contracts. Given the effort-inducing advantage of penalty contracts over bonus contracts documented by prior research, it is unclear why most organizations employ bonus contracts instead of penalty contracts. Indeed, Hannan et al. (2005) call for additional research to further understand the costs and benefits of each type of incentive contract. The purpose of this study is to examine whether contract completeness affects the effort-inducing efficiency of bonus contracts relative to penalty contracts. Specifically, we examine whether, in incomplete contract settings where trust is paramount to the agent's effort decision, bonus contracts, by creating a more trusting environment, can elicit greater effort as compared to penalty contracts.

Importantly, prior literature examining the effects of incentive contracts on agent effort (and agency theory in general) assumes a complete contract setting. A complete contract is one that fully specifies the obligations of the principal to provide monetary rewards to the agent for each potential future performance outcome. Moreover, these contractual terms can be enforced in a court of law (Baiman 1982). In such a setting, there is no discretion and, hence, no role for trust between the principal and agent (Casadesus-Masanell and Al-Najjar 2001). However, in practice, many incentive contracts are incomplete, allowing the principal some degree of discretion over the agent's monetary rewards. Discretion allows for opportunism on the part of the principal (e.g., Fisher et al. 2005) and, thus, introduces the possibility that the agent's trust in the principal will affect agent effort. Therefore, to the extent that contract frame—either bonus or penalty—affects the trust environment, the prior literature examining the effect of contract frame on employee effort is incomplete.

In this paper, we extend prior research by examining the effect of incentive contract framing in an incomplete contract setting. Whereas contract incompleteness can occur in various forms, in our setting, the contract is incomplete because it governs only one of two tasks for which the employee is responsible. Such settings are quite common because modern jobs are usually multi-faceted, with employees required to perform multiple tasks. These tasks vary in the degree to which their performance can be measured, and so when incentive contracts are used, they generally govern only a subset of the employees' tasks. In our laboratory setting, the agent performs an initial task for which performance-based payouts are enumerated by an incentive contract. We manipulate the incentive contract frame—either a bonus contract or a penalty contract—while maintaining economic equivalence between these contract types. We then introduce a second task that is not governed by the incentive contract and for which the principal has full discretion over the agent's compensation. With such discretion, trust becomes a potentially important determinant of agent effort on the second task. In this incomplete contract setting, we find that the contract frame manipulated in the first task affects effort measured in the second task in the opposite direction as that found in prior literature (e.g., Hannan et al. 2005), and this effect can be attributed to the effect of contract frame on the trust environment. Specifically, both trust and agent effort is lower in the penalty contract condition as compared to the bonus contract condition.

---

[1] While the use of bonus contracts has historically dominated that of penalty contracts, interest in and the use of contracts that combine elements of both bonuses and penalties, so-called "bonus-malus" contracts, is on the rise. For example, UBS AG executives and board members have been working under a bonus-malus contract since 2009 (Associated Press 2008). Use of bonus-malus contracts in the U.S. is also increasing as a result of U.S. legislators' promotion of "clawback provisions" aimed at excessive CEO compensation (e.g., Hosking 2008; Lublin 2010).

This study contributes to the framing literature by documenting that the effect of contract frame on employee effort depends on the nature of the contractual setting. Prior literature shows that under complete contracting, where there is no role for trust, employee effort is likely to be higher under a penalty contract as compared to a bonus contract (Hannan et al. 2005). However, in settings of incomplete contracting (e.g., where there is discretion in monetary payouts), trust plays an important role. Bonus contracts create a more trusting environment, and this effect can spill over to tasks not governed by the incentive contract, such that bonus contracts elicit greater effort on these tasks as compared to penalty contracts. This result is important to managers implementing incentive contracts because it suggests that both contract frame (e.g., bonus versus penalty) and the degree of contract incompleteness (e.g., the use of discretion) must be considered in designing incentive compensation plans.

This study also contributes to a second, separate stream of literature that examines the effect of formal controls, such as incentive contracts, on trust, an important informal control. In general, this literature documents the unintended negative effects of formal controls on trust (e.g., Das and Teng 1998, 2001; Enzle and Anderson 1993; Malhotra and Murnighan 2002). However, this literature generally focuses on negatively framed formal controls. By contrast, our results show that the effect of formal controls on trust will depend on whether the formal controls are *framed* positively or negatively, with the result that positively framed controls can actually increase agents' trust relative to no control.

The remainder of the paper is organized as follows: In Section II, we review relevant literature and develop the hypotheses. In Section III, we describe the experimental method. Results are provided in Section IV. Section V discusses implications of the study and provides areas for further research.

II. BACKGROUND AND THEORY DEVELOPMENT

A large body of literature examines how individuals' decisions are influenced by the way in which information is framed (e.g., Tversky and Kahneman 1981; Levin et al. 1998). Framing can occur on many dimensions. For example, Tenbrunsel and Messick (1999) examine whether decision makers frame a decision to invest in pollutant-reducing technology as a business decision or an ethical decision. They demonstrate that a formal sanction for the undesirable behavior of violating pollutant regulations causes decision makers to frame the technology investment decision as a business decision rather than an ethical decision, resulting in less technology investment and more regulatory violations.[2]

Accounting research focuses primarily on the positive versus negative framing of incentive contracts, providing insights into agent preferences for, and responses to, positively framed bonus contracts relative to negatively framed penalty contracts.[3,4] Luft (1994) shows that experimental participants have a propensity to choose a bonus contract over a monetarily equivalent penalty contract. She offers several interpretations of this result. First, participants may prefer a bonus over a penalty contract because of loss aversion (Kahneman and Tversky 1979), the notion that the disutility experienced from a loss is greater than the utility experienced from a gain of the same magnitude. Thus, participants have preferences for bonus contracts because subjective valuations of the monetary payoffs are greater under the gain frame induced by the wording of the bonus contract. Second, Luft posits that there are different *nonmonetary* benefits associated with bonus and penalty wording that affect agent preferences. Bonuses are associated with praise and reward, while penalties are associated with condemnation and disapproval, the former being preferred over the latter.

---

[2] For a thorough discussion of framing effects, see Levin et al. (1998).

Hannan et al. (2005) extend Luft (1994) by examining the effects of bonus versus penalty contracts on agent effort. The authors find that despite the agent's stated preferences for bonuses, as documented in Luft (1994), agents exert greater effort under penalty contracts. Hossain and List (2012) similarly find field evidence that workers in a Chinese high-tech manufacturing facility exert greater effort under a penalty contract relative to a bonus contract.

In both Hannan et al. (2005) and Hossain and List (2012), agents' effort choices are consistent with the loss aversion explanation of agent preferences for bonus contracts offered by Luft (1994). Specifically, the authors conclude that agents exert greater effort to avoid the loss associated with paying a penalty as compared to effort aimed at receiving the gain of a bonus. Importantly, however, Hannan et al. (2005) and Hossain and List (2012) are both conducted in a complete contract setting such that the contracts fully specify the agent payouts for each potential outcome; that is, the principal has no discretion over payouts. Yet, as Kreps (1990) notes, it is more characteristic of firms to have incomplete contracts, in which agents take actions without completely specified payouts from the principal. Luft (1994) uses the concept of incomplete contracts to offer a third interpretation for her finding of agent preferences for bonus contracts. Consistent with Kreps (1990), she acknowledges that contracts are typically incomplete, and that agents take actions, in part, based on potential monetary rewards, such as a discretionary bonus, for increased effort and performance beyond the contracted monetary rewards.

When contracts are complete, there is no discretion on the part of the principal and, hence, no effort-inducing role for trust between the principal and agent (Casadesus-Masanell and Al-Najjar 2001). However, when contracts are incomplete, as they are in most firms (Kreps 1990), the principal has some degree of discretion over the agent's monetary rewards, which allows for opportunism on the part of the principal (e.g., Fisher et al. 2005). In this setting—and in contrast to the complete contract setting of Hannan et al. (2005) and Hossain and List (2012)—the agent's trust in the principal becomes paramount in the agent's effort choice.[5] The question then becomes whether bonus and penalty contracts differentially affect the agent's trust in the principal. In the following paragraphs, we develop a theoretical model that describes the mechanisms by which

---

[3] See Bonner (2008) for a discussion describing accounting research focused on framing effects.

[4] The importance of framing as a characteristic of formal controls, more generally, is evident in the extant management control frameworks. For example, Jensen and Meckling (1992) include both positively framed outcome controls (i.e., "rewards") and negatively framed outcome controls (i.e., "punishments") as important control tools that organizations use to align incentives of managers with owners. Similarly, Ouchi and Maguire's (1975) outcome controls may be framed either positively (a bonus for goal achievement) or negatively (a penalty for lack of achievement). These and other frameworks (e.g., Merchant and Van der Stede 2007; Simons 1995) suggest that control framing is an important characteristic of formal control.

[5] While our primary construct of interest is trust, we acknowledge that this construct is highly related to other affect-based constructs such as fairness, perceived justice, or "liking" (Huang and Murnighan 2010). For example, accounting research (Kadous et al. 2011) demonstrates that auditors are more likely to trust advisors with whom they feel a strong personal affiliation. Therefore, it would be difficult, if not impossible, to fully separate trust from these other related constructs.

contract frame is expected to affect the trust environment and, ultimately, agent effort (see Figure 1).

Prior trust research has generally examined the effects of negatively framed formal controls. This research indicates that the implementation of a negatively framed formal control damages the trust environment (e.g., Das and Teng 1998; Enzle and Anderson 1993; Inkpen and Currall 1998; Malhotra and Murnighan 2002). Negatively framed controls damage the trust environment because they are perceived as being intrusive and as reducing the autonomy of the agent (Christ et al. 2008). Negatively framed controls often involve close observation or significant oversight, both of which may interfere with the agent's normal processes and activities and cause him or her to feel intruded upon. Further, negatively framed controls may limit the agent's decision rights, either directly, by curtailing certain behaviors, or indirectly, by attaching incentives to the outcomes of those decisions, leading to a perceived loss of autonomy.

Based on these general results, we likewise predict that framing an incentive contract negatively as a penalty contract will lead to perceived intrusion and a loss of autonomy by the agent. However, we posit that framing an incentive contract positively as a bonus contract will reduce, and perhaps even reverse, these adverse effects. Specifically, we expect that the agent's perception of intrusion (Figure 1, Path 1) and loss of autonomy (Path 2) will be lower under a bonus

contract than under a penalty contract. In fact, the agent may interpret the implementation of a bonus contract as a signal of the principal's intent to reward the agent for increased effort by sharing the resulting gains.

To the degree that an agent feels that controls intrude upon his or her actions and restrict his or her autonomy, these controls signal the principal's beliefs regarding the agent. Specifically, the principal's control choices signal the degree to which he or she questions the agent's integrity (Paths 4 and 6) and/or competence (Paths 3 and 5). First, by implementing controls that are more intrusive or more constraining on the agent's autonomy, a principal signals the expectation that the agent will intentionally engage in opportunistic behavior, such as shirking, cheating, stealing, etc. In this manner, the principal is sending a signal to the agent that he or she is questioning the agent's integrity. Second, more intrusive and more constraining controls may also indicate that the principal questions the agent's competence; that is, whether the agent is able to sufficiently complete the task or meet the required standards because of potential deficiencies in the necessary skill, aptitude, or tools, despite the agent's best intent and sufficient effort. Thus, the effect of contract frame will flow through, such that under a bonus contract, the agent will be less inclined to believe that the principal is questioning his or her competence and integrity than under a penalty contract.

To the degree that the agent believes his or her competence and/or integrity are being questioned, he or she will perceive less trust from the principal (Paths 7 and 8) (Das and Teng 2001). Further, because trust is reciprocal (Bradach and Eccles 1989; Gambetta 1988; Zand 1981), we expect the agent's trust in the principal to be higher under a bonus contract as compared to a penalty contract. Specifically, social projection theory suggests that individuals have a tendency to expect that others will behave similarly to themselves (Krueger 1998). According to this theory, the principal expects the agent to behave as he or she would and, thus, the principal's signal of trust in the agent reveals the principal's own trustworthiness to the agent. Therefore, by implementing a penalty contract that signals mistrust in the agent, the principal signals that he or she is likewise not trustworthy. In contrast, by implementing a bonus contract that signals trust, the principal provides a signal that he or she is trustworthy. Thus, agents working under a penalty contract will be less likely to trust the principal than will agents working under a bonus contract. That is, trust will be reciprocal (Path 9).

This reciprocity effect has been described in prior research that suggests that when one party feels (mis)trusted, it is likely to feel (mis)trust in return (e.g., Bradach and Eccles 1989; Gambetta 1988). For example, Christ et al. (2008) use an inter-organizational strategic alliance scenario to experimentally examine the effects of formal controls on trust. They show that formal controls have a negative effect on the controlled party's perceived trust (i.e., the extent to which the controlled party feels trusted by the controlling party), and a reciprocal negative effect on the controlled party's reciprocal trust in the controlling party. We extend this finding to the single firm, principal-agent setting. We predict that agents working under a penalty contract will perceive less trust and will, thus, reciprocate less trust relative to those working under a bonus contract.

In contrast to the complete contract setting of Hannan et al. (2005) and Hossain and List (2012), in our setting, the incentive contract does not govern all tasks. The principal has discretion over the agent's monetary rewards for the ungoverned tasks, allowing for opportunism on the part of the principal (e.g., Fisher et al. 2005). As a result, the agent's trust in the principal to reward the agent for effort becomes paramount in the agent's effort choice for the ungoverned tasks (Path 10). Because the agent's trust in the principal is damaged when the principal implements a penalty contract, the agent will have a pessimistic expectation of the extent to which effort will be rewarded by the principal's discretionary payout. By contrast, because the agent's trust in the principal is less damaged and instead is preserved or even enhanced when the principal implements a bonus contract, the agent will have a more positive expectation of the extent to which effort will be rewarded by the principal's discretionary payout.

Taken together (see Figure 1), we predict that agents working under a bonus contract will exert greater effort on tasks not governed by the incentive contract than will those working under a penalty contract.[6] This leads to our primary research hypothesis:

H1: In an incomplete contract setting, agent effort on tasks not governed by the incentive contract will be greater under a bonus contract as compared to a penalty contract.

III. EXPERIMENTAL METHOD

Experimental Design

We test our hypothesis and theoretical model using a computer-based experiment in an incomplete contract setting. Our experiment has two tasks, with performance-based pay for the first task defined by an incentive contract framed as either a bonus or penalty, depending on the experimental condition. Pay for the second task is at the complete discretion of the principal. We recruited 220 participants from graduate and undergraduate accounting classes of a highly ranked U.S. business school to participate in this study. Fifty-two percent of participants were female and 48 percent were male, and the average age was 20.4 years.

We use a 2 (Contract Frame) × 2 (Contract Implementation) plus 1 (Baseline) between-subjects experimental design to test our hypotheses. For our first variable—Contract Frame—we manipulate the type of contract that the principal has the option to implement for the first task: a positively framed contract that rewards agents for meeting performance targets with a bonus payment (hereafter, *bonus contract*), and a negatively framed contract that penalizes agents for missing the target (hereafter, *penalty contract*). We maintain monetary equivalence across contract frame conditions so that we can isolate the hypothesized framing effects from our model. The Contract Frame conditions are described in detail in the "Task 1 of the Experiment" subsection, below. The second variable—Contract Implementation (*Yes*, *No*)—is measured rather than manipulated, and represents the principal's decision to implement the incentive contract. Allowing the principal to select the contract is important because this choice signals the principal's trust in the agent (Christ 2012). As we will describe, our primary analysis relates only to the conditions in which the principal chose to implement the incentive contract. As a result, we do not analyze observations in the *bonus contract/no implementation* and *penalty contract/no implementation* conditions.

Finally, the "plus 1" condition is a baseline condition (hereafter, *fixed wage*) in which principals are not given the opportunity to implement an incentive contract for Task 1, and no bonuses or penalties are mentioned to the participants. The growing stream of literature examining the effects on trust of formal controls, including incentive contracts, compares agent behavior with and without formal control, taking as given a negatively framed formal control. To better reconcile our contract frame findings to this stream of literature, we include this *fixed wage* condition so that we can compare the effects on trust of the two contract frames versus a condition in which no incentive contract is imposed. Note that the agents in this *fixed wage* condition faced the same fixed wage contract as those in bonus and penalty conditions for whom the principals chose not to implement the incentive contract.

At the beginning of the study, each participant was randomly assigned to the role of either principal or agent and remained in the same role throughout the entire study.[7] Before beginning, the computer randomly matched participants into anonymous pairs of one principal and one agent.

---

[6] Lazear (1991) also suggests that bonus wording conveys an expectation of effort beyond a desired level, while penalty wording conveys an expectation for effort only up to a certain level. The differential expectations conveyed by the bonus contract will further serve to motivate greater effort on the part of the agent.

[7] To ensure that labels did not unnecessarily influence the behavior of participants, agent and principal participants were referred to as Participant A and Participant B, respectively, throughout the experiment.

Participants earned points based on the decisions that they and their partners made, as described below. The points were converted to cash and paid to the participants at the end of the study according to the following formula: U.S.$ Payment = (Points earned × 0.025). At the beginning of the study, each principal was endowed with 250 points, and each agent with 850 points in the *bonus contract* condition, and 1,000 points in the other conditions. These differential endowments reflect that over the course of the experiment, the principals had the opportunity to gain more net points than did the agents. Further, these different endowments ensure that when the principal chooses to implement an incentive contract, the *bonus contract* and *penalty contract* conditions are monetarily equivalent from the agent's perspective.

Task 1 of the Experiment

In Task 1, the agent selected a portfolio of investments for the principal.[8] That is, the principal earned the returns from the portfolio, but the agent chose the specific investments to be included in the portfolio and paid for the chosen investments from his or her endowment. While we acknowledge that in a real-world investment setting, the agent would not normally pay the cost of investments, this setting provides a useful laboratory scenario for testing our theory.[9] Specifically, we follow prior literature (e.g., Fehr et al. 1993) and use the cost of the investment to operationalize the agent's effort, which also allows us to vary that cost across the various investment opportunities.

Each agent was presented with 30 possible investments. From these 30 investment choices, the agent's task was to select and pay for one share each of ten investments. That is, the agent selected ten different investments, each of which earned points for the principal. The principal's expected returns were, thus, maximized if the agent selected shares of the ten investments with the highest expected returns in the next period.

There were two types of investments from which the agent could choose, "Bell" investments and "Whistle" investments.[10] Each Bell share cost the agent 10 points and each Whistle share cost the agent 25 points. Agents were provided with a graphical representation of the previous 19 periods of returns in the form of points per share for each of the 30 possible investments. Figure 2 depicts the history of points per share returned for one representative Bell (Panel A) and one representative Whistle (Panel B) investment.[11]

Whistle shares, while more expensive, had a higher average expected return. This was the basis of the control problem in the scenario. Specifically, the principals preferred that shares with higher returns, the Whistle shares, be selected, but the agents, who paid for the investments, preferred to

---

[8] For Task 1 of the experiment, we designed a cognitively challenging and engaging task for the agents, instead of using an abstract task as in the previous contract framing literature (e.g., Hannan et al. 2005). We chose this task because of the prior finding that formal controls influence employee trust because they are perceived to be intrusive and to limit the agent's autonomy (Christ et al. 2008). It is unlikely that these effects would manifest if agents engaged in an abstract effort choice.

[9] The contextualized economic games used to examine our research question are not intended as a literal representation of how firms do (or should) organize investment decisions. While the experimental task is an abstraction from reality, it is the theory that we wish to generalize. The design of this task is important in that it provides evidence about the theoretical constructs of interest despite any shortcomings it has in its reflection of mundane realism. For further discussion, see Friedman and Sunder (1994, 10–12) and Kachelmeier and King (2002).

[10] An alternative approach would have been to have the agent select between one Whistle and one Bell investment. We chose to have agents select ten investments (from a total of 30 investments) because we wanted the task to be intellectually stimulating to the agents. Specifically, in order to examine agents' beliefs about the intrusiveness and autonomy-limiting nature of the contract, it was necessary for them to be actively engaged in the task. Therefore, the task itself needed to be a significant undertaking and cognitively difficult.

[11] We constructed each investment's return history using either a long-term trend or a cyclical pattern, plus a noise parameter. Thus, the expected return for the next period was calculated as the expected value for the next point in the series given the underlying historical pattern.

FIGURE 2

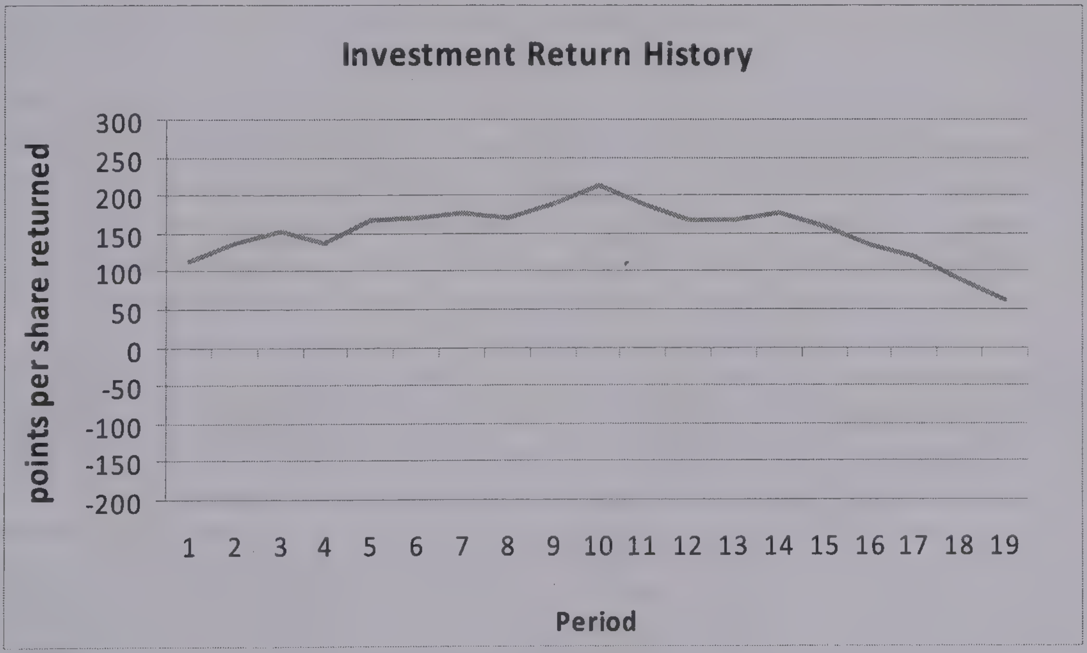
Panel B: An Example of the Investment History for One Whistle Investment



select the cheaper Bell shares. The expected return for the next period for Bell shares was, on average, 20 points per share across all Bell investments, whereas the expected return for the next period for Whistle shares was, on average, 50 points per share across all Whistle investments. Importantly, any individual investment could earn considerably more or less than the average.

Specifically, the expected return for the 15 individual Bell investments ranged from −8 to 48, and the expected return for the 15 individual Whistle investments ranged from −6 to 106.

In the two Contract Frame conditions, principals chose whether or not to implement an incentive contract prior to the agents' investment decision. Implementation of the incentive contract cost the principal 50 points. The incentive contract, if implemented, either established a bonus for the agent if total returns met or exceeded a minimum return (*bonus contract* condition), or established a penalty for the agent if total returns failed to meet a minimum return (*negative contract* condition). In the *fixed wage* condition, the principal was not given the opportunity to implement an incentive contract; that is, neither a bonus nor a penalty was mentioned to the participants.

In the *bonus contract* condition, if the principal elected to implement the incentive contract, the agent received an extra 150 points if the total return of all ten shares selected met or exceeded 500 points. No bonus points were paid to the agent if the total return was less than 500 points. The bonus was paid from the administrator's fund, not deducted from the principal's endowment.[12] Likewise, for the *penalty contract* condition, the agent was required to pay 150 points if the total return of all ten shares selected was less than 500. No penalty points were paid if the total return equaled or exceeded 500 points. The penalty was paid to the administrator's fund, not added to the principal's earnings. The *bonus* and *penalty contracts* provided monetarily equivalent incentives for the agents, so that any differences in reported trust perceptions following Task 1 or observed effort on Task 2 were due to the signaling effects of the contracts.[13] The summary of points that could be earned by each participant for Task 1 is presented in the experimental materials provided in Appendix A.

After the principal decided whether or not to implement an incentive contract, the agent was notified of this decision. At this point, the agent made the investment choices, and the investment payoff was determined by the administrator. Note, however, that actual returns were not revealed to participants until the end of the second task of the experiment. We withheld this information from all participants so that the agent's behavior on Task 2 would be influenced only by the framing of the contract imposed by the principal, and would not be affected by his or her earnings from Task 1.

Following Task 1, we solicited information using a post-experimental questionnaire. Participants responded to several questions intended to capture additional variables included in our formal model. Specifically, each agent indicated, on a 100-point Likert scale ranging from "not at all" to "a great deal," the extent to which he or she (1) felt that the principal questioned his or her integrity (Signal of Questioning Integrity), (2) felt that the principal questioned his or her competence (Signal of Questioning Competence), (3) felt that the principal trusted him or her (Perceived Trust),[14] (4) trusted the principal (Reciprocal Trust), (5) felt the principal intruded upon his or her decisions (Perceived Intrusion), and (6) felt he or she had decision-making autonomy (Perceived Autonomy).[15]

---

[12] This design choice ensured that the principal's cost of implementing the contract was held constant (at 50 points) across all conditions. An alternative approach would have been to have the principal pay from his or her account all costs, including the agent's total compensation (including wages, bonuses, and penalties) and to increase the principal's pay level to cover these costs. We chose not to take this approach because it would have complicated the experimental task considerably, and as long as the included costs were held constant across conditions, we are aware of no theories to suggest that this approach would affect our results.

[13] Note that the incentive contracts were designed to be fairly weak controls, in the sense that they do not provide the agent clear incentives to choose the optimal investment portfolio. This design choice, along with the absence of mutually observable actions, allows us to isolate the signaling effect of the contracts as distinct from the economic benefit documented in Coletti et al. (2005) and, thus, to investigate the difference between the signals engendered by the penalty contract as compared to the bonus contract.

[14] We follow prior literature and measure perceived and reciprocal trust using single-item Likert scale questions. However, we acknowledge that trust is a complex and difficult-to-measure construct and, therefore, this variable may capture other related factors, such as the perceived fairness of the principal, general effect, perceived justice, etc. To partially capture these constructs, we also include in our empirical model a direct path from Contract Frame to Perceived Trust (Figure 1, Link 11) that does not go through our theoretically motivated paths related to trust signaling (i.e., perceptions of intrusion, autonomy, questioning competence, and questioning integrity).

Task 2 of the Experiment

While the focus of Task 1 was on the effects of contract framing on perceived and reciprocal trust (Figure 1, Links 1–9, 11), Task 2 provided the primary dependent variable, Effort on Tasks Not Governed by the Incentive Contract. The principal's discretion over pay for Task 2 made the agent's trust relevant (Figure 1, Link 10). In Task 2, participants retained the same partners and roles, and continued with the same contextual setting in which agents made investments on behalf of principals. Each participant began Task 2 with the total number of points he or she had at the end of Task 1 following the investment decisions made by the agent. Although the participants did not know the exact number of points they had earned up to this point because they had not yet been told the returns from the shares selected by the agent, they were told that each agent had a minimum of 600 points with which to make an additional investment, as guaranteed to be the case by design.

Task 2 was a contextualized version of the standard "trust game," as defined by McCabe et al. (2003), with the agent moving first and the principal moving second. In Task 2, the agent made an additional investment for the principal. This investment decision was different from the prior investment decisions in several important ways. First, there was only one type of investment, a "Horn" investment, which cost the agent 10 points per share, whereas in Task 1, some investments cost 10 points and some cost 25 points per share. Second, the return per Horn share investment was known to be 30 points, whereas in Task 1, the return per share was uncertain, with expected returns based on the history of past returns. Third, the agent could purchase from zero to 50 shares of the Horn investment, whereas in Task 1, the agent could only select one share each of ten different investments. Note that the guaranteed bank of 600 points for each agent is enough to invest in the full 50 Horn shares at 10 points per share.

The agent's choice of the number of Horn investments to make is our measure of costly agent effort. We follow a large literature that operationalizes agent effort using a costly choice (e.g., Fehr et al. 1993), based on the simplifying assumptions of analytical models that individuals have utility for wealth and leisure (see Baiman 1982).[16] Importantly, investing in Horn shares is an effort choice that is controlled by the agent, results in disutility (because the cost of the shares is borne by the agent), and is correlated positively with output in the form of the principal's return. Thus, the investment in Horn shares meets the definition of effort used in the agency theory literature, as outlined by Baiman (1982).

As in Task 1, the principal earned the returns from the portfolio, equal to 30 points × the number of shares of the Horn investment purchased by the agent. As in the standard trust game, after learning how many shares the agent purchased, the principal could then pay any amount of the

---

[15] Several recent studies have examined whether eliciting participants' beliefs about trust prior to a traditional trust game affect subsequent trusting behavior (Guerra and Zizzo 2004; Zizzo 2008). Results of these studies indicate that participants' trusting behavior exhibited in the trust game does not differ significantly when beliefs are elicited as compared to conditions when there is no belief elicitation.

[16] The first mover investment in a trust game is a widely used measure of behavior within a trust environment (Camerer 2003, 85–100). We employ the first mover investment as a simple and straightforward measure of effort. Alternative design choices for this experiment would require less reliable measures of effort (e.g., time spent on the task) that are likely to be affected by other factors outside of the experiment (e.g., a preference for completing the experiment quickly). Recent research in accounting has compared the operationalizations of effort as cost with real-effort tasks in an experiment on reciprocity, and finds that people react similarly to both operationalizations of effort (Bruggen and Strobel 2007). Although prior literature consistently operationalizes effort as a linearly increasing cost to the agent, we acknowledge that the cost of effort is not necessarily linear and that this is a limitation of this research design.

[a] The number of participants is twice the number of observations reported here because one observation requires two participants.

[b] This column includes observations from the *fixed wage* condition, but not those from the *penalty* and *bonus contract* conditions when the principal chose not to implement the incentive contract.

[c] We report the descriptive statistics only from those dyads in which the principals chose to impose the incentive contract because these are the observations used for our hypothesis test.

[d] Effort is measured using the number of Horn shares A Participants purchased during Task 2 of the experiment.

[e] Participants responded to the following questions using a 100-point Likert scale:

- To what extent do you feel that Participant B has intruded on your decisions? (Perceived Intrusion)
- To what extent do you feel that you have the autonomy to make decisions? (Perceived Autonomy)
- To what extent do you feel that Participant B questions your competence? (Signal of Questioning Competence)
- To what extent do you feel that Participant B questions your integrity? (Signal of Questioning Integrity)
- To what extent do you feel that Participant B trusts you? (Perceived Trust)
- To what extent do you trust Participant B? (Reciprocal Trust)

return back to the agent, such that monetary payouts for agent effort are at the complete discretion of the principal. Importantly, the principal could choose to keep all of the returns and pay nothing to the agent. Thus, the principal had the opportunity to behave opportunistically, making the agent's trust in the principal an important determinant of the agent's chosen effort.

Without obligation to return anything, standard economic theory predicts that the principal would pay none of the Horn investment returns to the agent. Anticipating this, the agent would not invest in any Horn shares; i.e., exert no effort. Thus, any positive level of effort in the form of investment by the agent in costly Horn shares critically depends on the level of the agent's trust in the principal to return at least the cost of the Horn shares (McCabe et al. 2003).

Following completion of Task 2, participants were given a questionnaire that included demographic information and manipulation checks regarding the extent to which they understood the tasks completed. Participants received their respective payoffs resulting from decisions made in both parts of the experiment and were dismissed. Descriptive statistics for variables defined above are provided in Table 1.

IV. RESULTS

Hypothesis Test

Our primary interest is in examining the effect of contract frame on effort for a task not governed by the incentive contract. Our primary test of H1 compares effort on Task 2 (i.e., the number of Horn shares purchased) when the principal chose to implement the bonus contract, to effort when the principal chose to implement the penalty contract. Thus, for this analysis, we ignore the *fixed wage* condition, as well as those observations in the *bonus contract* and *penalty contract* conditions for which the principal chose not to implement the incentive contract. Consistent with H1, agents exert greater effort in the *bonus contract* condition than in the *penalty contract* condition (see Table 1, means = 33.92 and 21.44, respectively). This difference is statistically significant ($t = 12.48$, $p < 0.01$). Thus, when a task is not governed by the incentive contract, we find that the contract frame affects agent effort in the opposite direction to that found in prior literature (e.g., Hannan et al. 2005). To further assess whether the effort difference between the bonus and penalty contract conditions can be attributed to the hypothesized effect of contract frame on the trust environment, we test the complete theoretical model depicted in Figure 1 in the following section.

Test of Complete Theoretical Model

We use structural equations-based path analysis to estimate our theoretical model depicted in Figure 1. Note that in addition to the ten model paths described in the theoretical development of H1, we also include in the model an additional path by which bonus and penalty contracts differentially affect the trust environment, separate from the posited signaling path that is our primary focus (Figure 1, Path 11). This additional general path captures other affect-based constructs by which contract framing may affect the trust environment.[17] We acknowledge, however, that this path will likely only partially capture these constructs, as their influence might also be embedded in the signaling path.

To assess the model, we conduct a test of goodness of fit. The Comparative Fit Index (CFI), a measure of the proportion of improvement of the fit of our model to the null model, is 0.965, which is above the generally accepted minimum value of 0.95 (Byrne 2001). We further confirm the model's goodness of fit with a traditional Chi-square test ($\chi^2 = 10.76$, $p = 0.71$), and an Incremental Fit Index (1.02) that is above the recommended minimum of 0.95 (Byrne 2001). Thus, the model provides a good fit for describing the relations in the data.

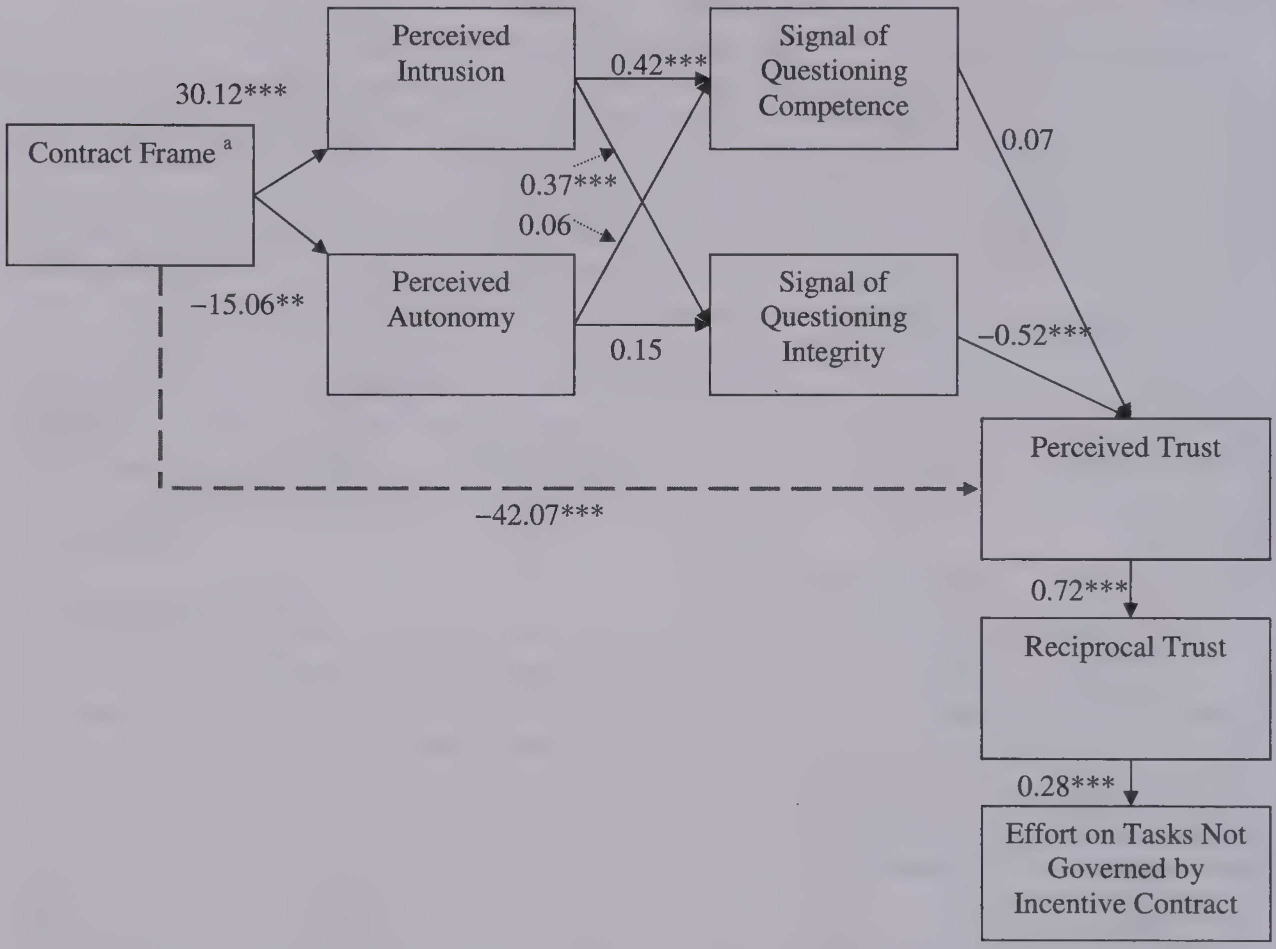
The standardized path coefficients and statistical significance are presented for the estimated model in Figure 3. As expected, results indicate that participants perceive a greater sense of intrusion (30.12, $p < 0.01$) and less autonomy (−15.06, $p < 0.05$) under a penalty contract than under a bonus contract. Greater Perceived Intrusion is positively associated with the Signal of Questioning Competence (0.42, $p < 0.01$) and the Signal of Questioning Integrity (0.37, $p < 0.01$). In addition, when the agent feels that his or her integrity is being questioned, Perceived Trust is reduced (−0.52, $p < 0.01$).[18]

---

[17] Affect is a response to a stimulus that presents as either a positive or negative mood or emotional reaction (Fiske and Taylor 1991). While, to our knowledge, prior research does not examine an affective reaction to control system implementation, research in accounting does document that affective reactions can have significant effects on capital budgeting (Kida et al. 2001; Moreno et al. 2002; Sawers 2005) and inventory valuation decisions (Chung et al. 2008).

[18] The effect of contract frame on perceived trust flows through the signal that the principal is questioning the agent's integrity rather than the agent's competence. This is likely because this study examines incentive contracts, which are a form of outcome control. Formal controls can affect behavior by providing both motivation and direction (Merchant and Van der Stede 2007). Outcome controls, while being an effective motivational tool, are less useful for providing direction than are behavior controls. Therefore, outcome controls, regardless of whether they are positively or negatively framed, are less likely than behavior controls to be interpreted as a signal that the principal is questioning the agent's competence.

FIGURE 3
Test of Full Model: Comparison of Penalty and Bonus Contract Conditions



,* Indicate significance at the 0.05 and 0.01 levels, respectively (one-tailed).

This figure shows the results of the path analysis. The standardized path coefficient and corresponding one-tailed significance are shown next to each path. Goodness of fit is measured through the Comparative Fit Index (0.965), which is above the generally accepted minimum value of 0.95 (Byrne 2001) and confirmed with a traditional Chi-square test ($\chi^2 = 10.76$, $p = 0.71$), an Incremental Fit Index (1.02), and a Root Mean Square Error of Approximation (0.00).

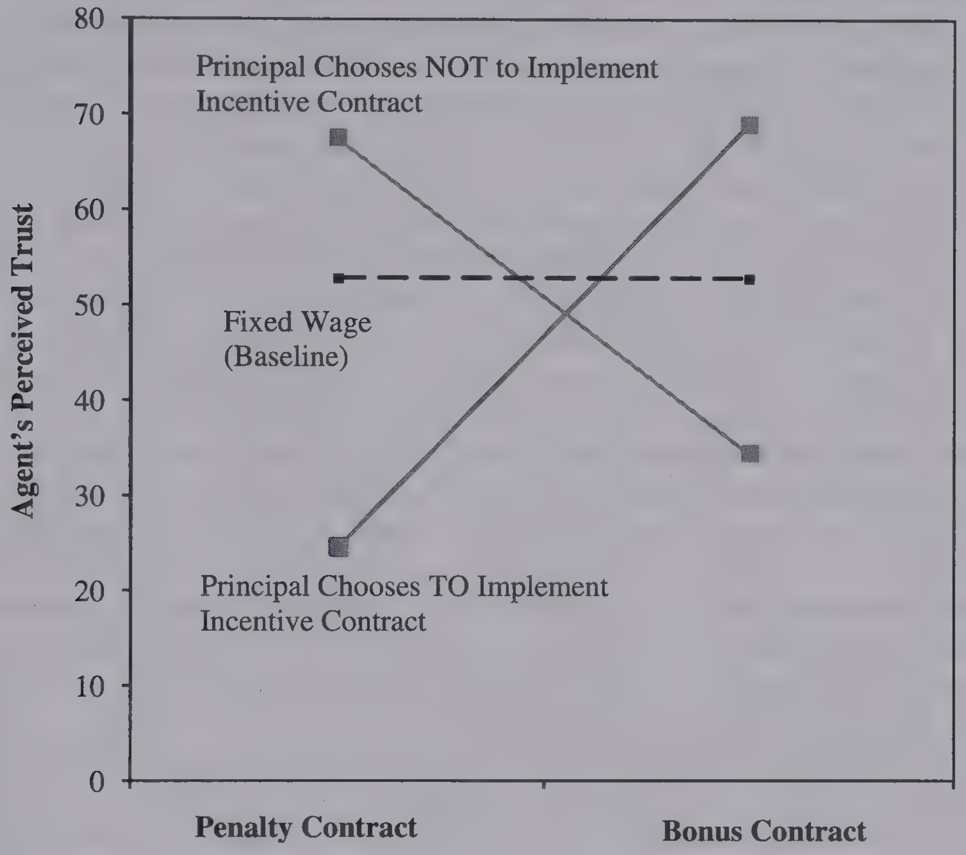
[a] The data used in this analysis include observations only from the *penalty* and *bonus contract* conditions when the principal chose to implement the incentive contract. Contract Frame assumes a value of 0 for the *bonus contract* condition, and 1 for the *penalty contract* condition.

The results also show that trust is reciprocal. As the agent's Perceived Trust increases, his or her Reciprocal Trust for the principal also increases (0.72, $p < 0.01$). Finally, when we test the link between the agent's Reciprocal Trust and the agent's Effort on Task 2, we find the expected positive relation between the agent's Reciprocal Trust and the agent's Effort (0.28, $p < 0.01$). The general path from Contract Frame to Perceived Trust is negative and significant (−42.07, $p < 0.01$), documenting a negative effect on trust of a penalty contract as compared to a bonus contract, incremental to the signaling effect we hypothesize. While not the primary focus of our study, we expect that this path may reflect a more negative affective reaction to the implementation of the penalty contract as compared to the bonus contract.

In sum, consistent with our expectations, the penalty contract has a negative effect on the trust environment, and this effect spills over to tasks not governed by the incentive contract, such that

FIGURE 4

Supplemental Test of Agent's Perceived Trust under the Bonus and Penalty Contract Conditions versus the Fixed Wage (Baseline) Condition



This figure shows the average agents' Perceived Trust across conditions and across the decisions of principals to implement or not implement the incentive contract. The average Perceived Trust in the *fixed wage condition* (in which the principal was not given the opportunity to implement an incentive contract) is represented by the horizontal line labeled "Fixed Wage (Baseline) Condition." The other two lines on the graph represent the Perceived Trust reported by agent participants in the *penalty* and *bonus contracts* conditions. Specifically, the positively sloped line represents agents' Perceived Trust when principals chose to implement the contract, and the negatively sloped line represents agents' Perceived Trust when principals chose not to do so.

bonus contracts elicit greater effort on these tasks as compared to penalty contracts. This effect occurs both through the signaling effect we posit, as well as through an additional link that captures other mechanisms, such as perceived unfairness or negative affect. Thus, contrary to prior research on contract framing, we document that in an incomplete contract setting when the agent is vulnerable to the principal's decisions and, therefore, must exhibit trust when determining his or her effort level, penalty contracts lead to diminished effort.

Supplementary Tests

Comparison to Fixed Wage (Baseline) Condition

In our *fixed wage* condition, where no incentive contract is available for implementation, the average Perceived Trust is 52.83 on a 100-point Likert scale, which we represent in Figure 4 by the horizontal dashed line. The other two lines on the graph represent the Perceived Trust reported by agent participants in the *penalty contract* and *bonus contract* conditions. The positively sloped line represents agents' Perceived Trust when principals chose to implement an incentive contract, and the negatively sloped line represents agents' Perceived Trust when principals chose not to do so.

Because our primary interest is in examining the effects of contract frame on trust and effort, our main analysis compares the two points on the upward-sloping line. That is, we compare the situation in which the principal has chosen to implement a bonus contract to the situation in which he or she has chosen to implement a penalty contract. We include the *fixed wage* condition for benchmarking purposes. Our analyses ignore the points on the downward-sloping line, which reflects the principal's choice to not implement an incentive contract, for two reasons. First, in typical business settings, employees would not be aware of an explicit choice to not implement an incentive contract. Second, a practical reason for ignoring the downward-sloping line is that the number of observations is quite low. Recall that these observations are the byproduct of the principal's endogenous choice of whether to implement an incentive contract; a choice crucial to the experimental design (cf. Christ 2012). However, because only seven principals in the *bonus contract* condition and 24 principals in the *penalty contract* condition chose to not implement the contract, any conclusions drawn from these observations would be unreliable.

By including the *fixed wage* condition, we are able to compare our results to prior studies examining the effects of formal control on trust (e.g., Das and Teng 1998, 2001; Enzle and Anderson 1993; Malhotra and Murnighan 2002). As previously described, this literature generally finds a negative relation between formal control and trust, suggesting that there are unintended consequences to implementing a formal control; namely, the degradation of the trust environment, which ultimately diminishes firm performance. However, this literature focuses on negatively framed formal controls, such as a penalty contract or audits of performance, and has not considered the effects of positively framed formal controls, such as a bonus contract.

Consistent with the prior literature, we find that relative to the *fixed wage* condition, the *penalty contract* condition results in lower levels of both Perceived Trust and Reciprocal Trust (see Table 1), and all contrasts are statistically significant at $p < 0.01$ (untabulated). Thus, we confirm that penalty contracts, which are negatively framed formal controls, do have unintended consequences of diminished trust. However, Perceived Trust is significantly higher in the *bonus contract* condition than in the *fixed wage* condition, at $p < 0.05$ (untabulated). There is no statistically significant difference between the *bonus contract* and *fixed wage* conditions for Reciprocal Trust. The results of these comparisons indicate that contrary to prior research, which did not differentiate between control frames, when *positively* framed formal controls are imposed, there is no degradation (and in the case of Perceived Trust, there is actual enhancement) of the trust environment.

Principal Implementation Decisions

While our main goal is to examine the effects of contract frame on the trust environment and agent effort, our data also provide insight into the contract implementation decisions of the principals. Principals appear to strategically anticipate the effect of their contract choice on agent behavior. Specifically, 78 percent (25 of 32) of principals in the *bonus contract* condition chose to implement the contract, compared to 49 percent (24 of 49) in the *penalty contract* condition. Thus, principals are more likely to choose to implement the Task 1 incentive contract when doing so is more likely to lead to higher effort in Task 2 (untabulated, $F = 6.34$, $p < 0.05$).

V. DISCUSSION AND SUGGESTIONS FOR FUTURE RESEARCH

Organizations implement incentive contracts to induce desirable employee effort. While incentive contracts framed as bonuses and penalties are found in practice, bonus contracts are much more prevalent. Accounting research examining the effects of contract frame finds that despite employees' stated preferences for bonus contracts, employees exert greater effort under penalty contracts, resulting in greater firm profitability when penalty contracts are employed (Hannan et al. 2005; Hossain and List 2012). Thus, there has been a disconnect between the dominance of bonus contracts in practice with these prior research findings. Importantly, we note that prior literature on contract framing assumes a complete contract setting. In practice, employment contracts are often incomplete, leaving some components of employee pay to the discretion of the principal. In such incomplete contract settings, an agent's trust in his or her principal is an important determinant of effort.

This study examines the effect of contract framing on effort in an incomplete contract setting and, thus, considers trust as a mediating variable. We find evidence that for a task not governed by the incentive contract, agents exert greater effort under bonus contracts relative to penalty contracts. Analysis of a comprehensive theoretical model we developed based on the formal control/trust literature reveals that the relation between contract frame and effort depends on the level of trust induced by the implementation of a bonus or penalty contract.

The results of this study contribute to the incentive contract framing literature and help explain why bonus contracts are more common in practice than penalty contracts, despite evidence that penalty contracts elicit greater effort. Our findings suggest that it is important to consider both the bonus versus penalty contract frame and the completeness of the contract when designing incentive compensation plans.

The results of this study also contribute to a second stream of literature examining the effects of formal controls, such as incentive contracts, on trust. Studies in this stream of literature often conclude that formal controls have unanticipated consequences of deteriorating the trust environment, resulting in lower effort. However, this literature has focused primarily on negatively framed formal controls, such as penalty contracts, but has not considered the effects of positively framed formal controls, such as bonus contracts. Our results reveal that the frame of the formal control influences whether the control is perceived by the agent to be a signal of distrust and affects agent behavior.

The results of this study suggest several avenues for future research. First, this study and several prior studies on the effects of incentive contract framing (e.g., Luft 1994; Hannan et al. 2005) analyze the various mechanisms through which framing may influence agent behavior. However, because each study focuses on a different mechanism, it is unclear when the effect of one mechanism might outweigh the others and when managers should implement a bonus versus a penalty contract. Future research should explore these mechanisms further to determine in which settings the effect of each mechanism is likely to dominate.

Second, although the principals in our study choose whether or not to impose an incentive contract, the framing of the contract available to the principal in each condition is determined exogenously by the experimenters. In practice, principals choose whether to frame an incentive contract as a bonus or penalty. It is possible that the endogeneity of the framing decision might moderate agents' response to it, resulting in more positive or more negative reactions to an endogenously chosen bonus or penalty contract. This should not pose a threat to the validity of our study, because it works against our finding results. However, future research should consider both the agent's response to the contract frame chosen by management, as well as the factors that the principal considers when choosing the contract frame. Similarly, research examining the characteristics of principals who choose bonus versus penalty contracts may be fruitful. For example, are certain types of principals more likely to be trusting, and do they, therefore, exhibit a consistent preference for bonuses or penalties?

Third, we document a somewhat surprising result that the implementation of a bonus contract positively influences perceptions of being trusted, separate and distinct from the signaling effect we hypothesize. While not the focus of this study, the reasons for this result are worthy of additional study. One possibility is that agents' preference for fairness results in a favorable reaction to the bonus contract. A second possibility is that agents have a general affective reaction to this type of formal control. Managers often rely on affective evaluations as a basis for making judgments (Schwartz 2002). This "affect heuristic" may moderate the effect of contract framing on perceived trust. Our results may suggest that, incremental to the negative signaling effect we posit, negatively framed formal controls create negative affect, deteriorating the trust environment. Positively framed controls, on the other hand, appear to induce positive affect, leading to greater trust. The investigation of this result is a promising area for future research.

Fourth, our experiment constitutes a one-shot trust game. Although the results show that effort is highest when a bonus contract is implemented, it is unclear whether this benefit would remain if the principal/agent pairs engaged in repeated trust games. Future research could investigate whether contract frame continues to influence effort even after the principal has had the opportunity to take advantage of the agent's trust.

Finally, our model is based on agents' beliefs regarding principals' motivation for implementing the incentive contract. However, prior research suggests that if agents do not interpret the implementation of the formal control as a signal of distrust, they will not respond negatively (Christ 2012). Therefore, future research should consider whether the effects of the bonus and penalty contracts found in the current paper hold if the principal is able to credibly signal that he or she trusts the agent.

APPENDIX A
EXPERIMENTAL INSTRUMENT

General Instructions for All Conditions

INSTRUCTIONS

Participant #: ___________

GENERAL

You are about to participate in a study on decision making. Please read these instructions carefully, because the amount of money you earn will depend in part on your decisions. Also, there will be several short quizzes on these instructions to ensure your understanding, and you will not be able to continue until you accurately complete the quizzes, so please pay close attention.

If you have any questions, you should first read back through the instructions. If you continue to have questions after all the instructions are read, please raise your hand and the Administrator will answer you in private.

Unless you are asking a question to the Administrator in private, **please do not talk** at all, during this experiment.

OVERVIEW OF THE STUDY

This is a computerized decision making study. We expect the entire session to last approximately 60 minutes, during which time you will be required to answer questions and make decisions.

In this study, you will assume the role of either Participant A or Participant B. You will remain in the same role throughout the entire study. We will tell you which role you will assume after you read the first set of instructions.

Before you begin, the computer will randomly match participants into pairs (of one Participant A and one Participant B). The pairings are anonymous. You will not be told who you are paired with either during or after the study.

You will earn points, which can be affected by decisions made by you and/or the person with whom you are paired. These points will be converted to cash and you will be paid the cash amount before you leave today. Points will be converted to cash using the following formula:

US \$ Payment = (Points earned X .025)

Task 1 Overview for [Bonus Contract] [Penalty Contract] [Fixed Wage] Conditions

Initial Decisions

Overview

As a first step, Participant A will have the task of selecting a portfolio of investments for Participant B. That is, Participant B will earn the returns from the portfolio, but Participant A will choose the specific investments to be included in the portfolio. Participant A will also pay for the investments, but will be given a fund from which to pay. More specifically, at the start of the study,

- **Participant A** will be given [850] [1,000] [1,000] points, and
- **Participant B** will be given 250 points.

Participant A's initial fund is larger, because Participant A must pay for the investments and Participant B will receive the returns from the investments.

The following instructions will describe in detail the decisions made by Participant A and Participant B. Because you do not yet know to which role you will be assigned, it is important for you to pay close attention to both sets of instructions.

Task 1 Agent Investment Decision Description for All Conditions

Participant A

Participant A has the task of selecting the portfolio of investments. Participant A will be presented with 30 possible investments. From these 30 investment choices, Participant A ***must select and pay for 1 share each of 10*** of these investments, which will earn points for Participant B. Participant B will hold the shares for one period only, and so Participant B's returns will be maximized if Participant A selects the 10 shares that are expected to make the highest returns in the next period.

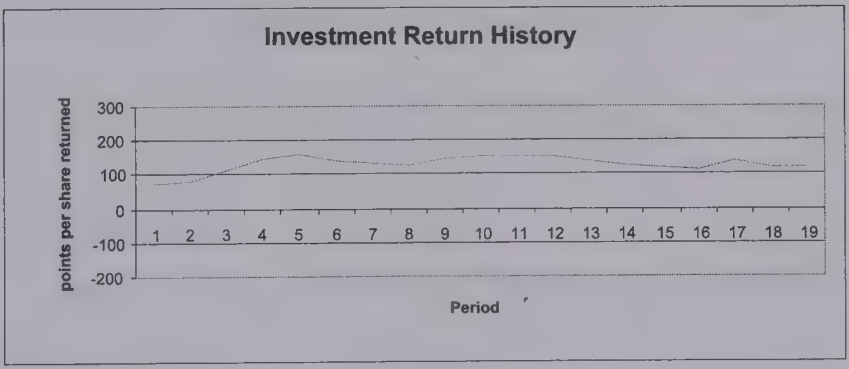
NOTE: Participant A must select 10 *different* investments, and buy exactly *one share* of each of these investments.

There are two types of investments, 🔔 (bell) investments and 📯 (whistle) investments. The cost per share depends on the investment type:

- Each 🔔 (bell) share selected will cost Participant A 10 points.
- Each 📯 (whistle) share selected will cost Participant A 25 points.

📯 (whistle) shares are more expensive, because on average they are expected to return more per share in the next period. Specifically, 🔔 (bell) shares will earn an average return of 20 points per share, whereas 📯 (whistle) shares will earn an average return of 50 points per share. Importantly, this is only an average, and any individual investment can earn considerably more or less than the average (as you can see by looking at the graphical representations of the investment return history, which are provided to you on the large, folded documents enclosed, and described below).

Both participants will be provided with a graphical representation of the previous 19 periods of returns (points per share) for each of the 30 possible investments. For example, the history of points per share returned for one investment available for selection might look like this:



[Below for Bonus Contract and Penalty Contract Conditions Only]
Participant B will have the opportunity to implement a control system prior to Participant A's investment decision. The control system, if implemented, establishes a [bonus] [penalty] system for Participant A in which Participant A will [receive an extra 150 points if the total return of all shares chosen by Participant A meets or exceeds 500 points] [be required to pay 150 points if the total return of all shares chosen by Participant A is less than 500]. [No bonus points would be paid to Participant A if total return is less than 500 points.] [No penalty points would be paid if total return equals or exceeds 500 points.] The [bonus] [penalty] will be paid [from] [to] the administrator's fund. That is, the [bonus] [penalty] will not be [deducted from] [added to] Participant B's fund.

After Participant B decides whether or not to implement a control system, Participant A will be notified of this decision.

Task 1 Summary of Participant A Points Earned for [Bonus Contract] [Penalty Contract] Conditions

Summary of Points – Participant A

Participant A will receive an initial fund of [850] [1,000] points. From this fund, Participant A will pay for the 10 shares selected (10 points for each 🔔 (bell) share and 25 points for each 📯 (whistle) share). Further, the points will depend on whether or not Participant B chose to implement a control system and, if a control system has been implemented, the total return of the shares chosen by Participant A. Thus, the payoffs to Participant A for this initial decision are as follows:

	No control system	Control system
Total Share Returns < 500	[850 points - Cost of Shares] [1,000 points - Cost of Shares]	[850 points - Cost of Shares] [1,000 points - Cost of Shares - 150 penalty points]
Total Share Returns >= 500	[850 points - Cost of Shares] [1,000 points - Cost of Shares]	[850 points - Cost of Shares + 150 bonus points] [1,000 points - Cost of Shares]

For example, suppose Participant B implements the control system and Participant A chooses 6 🔔 (bell) shares and 4 📯 (whistle) shares. Also assume that the returns for these investments [exceed] [are less than] 500 points. Participant A's payoff will equal [850 – (6 X10) – (4 X 25) + 150 = 840 points] [1000 – (6 X10) – (4 X 25) - 150 = 690 points].

If Participant B does not implement the control system, or the returns for the investments [are less than] [exceed] 500, Participant A's payoff will equal [850-(6X10) – (4 X 25) = 690] [1000-(6X10) – (4 X 25) = 840].

Task 1 Summary of Participant A Points Earned for Fixed Wage Condition

Summary of Points – Participant A

Participant A will receive an initial fund of 1000 points. From this fund, Participant A will pay for the 10 shares selected (10 points for each 🔔 (bell) share and 25 points for each 📯 (whistle) share).

For example, suppose Participant A chooses 6 🔔 (bell) shares and 4 📯 (whistle) shares. Participant A's payoffs will equal: 1000 – (6 X10) – (4 X 25) = 840 points.

Task 1 Principal Contract Implementation Decision Description for [Bonus Contract] [Penalty Contract] Conditions (omitted for Fixed Wage condition)

Participant B

Participant B will receive the total return from the 10 (ten) shares chosen by Participant A.

As described in the instructions for Participant A, Participant B will have the opportunity to implement a control system prior to Participant A's investment decision. The control system, if implemented, establishes a [bonus] [penalty] system for Participant A.

If Participant B chooses to implement a control system, the cost to Participant B is 50 points.

Task 1 Summary of Participant B Points Earned for [Bonus Contract] [Penalty Contract] Conditions

Participant B

Participant B will receive the total return from the 10 (ten) shares chosen by Participant A.

As described in the instructions for Participant A, Participant B will have the opportunity to implement a control system prior to Participant A's investment decision. The control system, if implemented, establishes a [bonus] [penalty] system for Participant A.

If Participant B chooses to implement a control system, the cost to Participant B is 50 points.

Summary of Points – Participant B

The total number of points that **Participant B** earns will depend on the total return of the shares chosen by Participant A, and whether or not Participant B chose to implement the control system. Thus, the payoffs to Participant B are as follows:

	No control system	Control system
Total Share Returns< 500	250 points + total share returns	250 points + total share returns - 50 points for cost of control system
Total Share Returns >= 500	250 points + total share returns	250 points + total share returns - 50 points for cost of control system

Task 1 Summary of Participant B Points Earned for Fixed Wage Condition

Summary of Points – Participant B

The total number of points that **Participant B** earns will depend on the total return of the shares chosen by Participant A. Specifically, Participant B will earn 250 points, plus the total returns from the shares chosen by Participant A. That is:

Participant B points = 250 points + total return on shares chosen by Participant A

Task 2 Overview for All Conditions

CONTINUING DECISIONS

Overview

You are still in the same role as before – either Participant A or Participant B.

In addition, you are paired with the same person. The identification of participants will continue to be anonymous throughout the study.

You will start this part with whatever points you have in your fund following the prior set of decisions. (Note that you don't know the amount exactly, because we have not told you the returns from the shares selected by Participant A. However, each Participant A still has a minimum of 600 points with which to make investments.)

You will now have the opportunity to earn more points based on the choices made by you and the person with whom you are paired.

Participant A

Participant A now has the task of deciding on one additional investment for Participant B. This investment decision is different from the prior investment decisions in several important ways:

1. There is only one type of investment: a 📯 (horn) investment.
2. Each 📯 (horn) share costs 10 points (whereas in prior decisions, some investments cost 10 points and some cost 25 points).
3. The return per share in the next period is known to be 30 points (whereas in the prior decisions, the return per share in the next period was unknown, and had to be predicted based on the history of past returns).
4. Participant A can purchase anywhere from 0 to 50 shares of the 📯 (horn) investment (whereas in the prior decisions, Participant A could only select one share each of 10 different investments).
5. Participant B will earn the returns from the portfolio. ***However, Participant B will have the opportunity to share the return from the investment with Participant A (whereas in the prior decisions, Participant B kept the total return).***

Participant B

After learning how many shares Participant A purchased, **Participant B** will be given the opportunity to pay any amount of the return to Participant A. The return will equal 30 points X the number of shares of the 📯 (horn) investment purchased by Participant A, and Participant B can share (i.e., give back) anything from 0 to the total return with Participant A.

Analysts' Motives for Rounding EPS Forecasts

Patricia M. Dechow
University of California, Berkeley

Haifeng You
The Hong Kong University of Science and Technology

ABSTRACT: We investigate analysts' motives for rounding annual EPS forecasts (placing a zero or five in the penny location of the forecast). We first show that an intuitive reason for analysts to engage in rounding is in circumstances where the penny digit of the forecast is of less economic significance. By rounding, analysts reveal that their forecasts are not intended to be precise to the penny. We also show that analyst incentives impact the likelihood of rounding. Specifically, we predict that analysts will exert less effort forecasting earnings for firms that generate less brokerage or investment banking business since such firms create less value for the analysts' employers. As a consequence of this reduced effort and attention, the analyst will be more uncertain about the penny digit of the forecast and so will round. Our results are consistent with this prediction. One implication of our findings is that a rounded forecast is a simple and easily observable proxy for a more noisy measure of the market's expectation of earnings. Consistent with this implication, we show that rounded forecasts bias down earnings response coefficients at earnings announcements.

Keywords: *rounding; analyst effort; brokerage; investment banking; earnings forecasts; earning response coefficient.*

I. INTRODUCTION

Rounding a number is replacing it with another value that is approximately equal but is a shorter or a simpler representation. Rounded numbers require less cognitive effort to remember and communicate. As a result, humans exhibit a strong psychological preference for rounded numbers. This phenomenon, known as "heaping," has been documented in the psychology, finance, and statistics literatures (e.g., Huttenlocher et al. 1990; Harris 1991; Brown et al. 1998; Roberts and Brewer 2001; Pope and Simonsohn 2011).

We appreciate the comments of Philip Brown, Yunhao Chen, John Harry Evans III (senior editor), Keith Godfrey, Charles Lee (editor), two anonymous referees, workshop participants at the University of Boston, University of British Columbia, The Hong Kong University of Science and Technology, University of Maryland, Peking University, Santa Clara University, University of Western Australia 2010 Conference, and 2010 AAA Annual Meeting in San Francisco.

Editor's note: Accepted by Charles Lee.

Submitted: June 2011
Accepted: June 2012
Published Online: June 2012

Financial analysts appear to exhibit a similar preference for rounded numbers when they forecast earnings. Herrmann and Thomas (2005) document that approximately 55 percent of annual EPS forecasts on I/B/E/S from 1985 to 2001 end with a zero or five in the penny location (the unconditional expected percentage should be around 20).[1] Given that earnings per share is a widely used input in equity valuation and investment decision making, it would seem that the economic importance of a precise forecast would dwarf the benefits of providing a rounded number that is easy to remember. Therefore, cognitive ease is unlikely to be the primary reason for rounding by analysts. An alternative explanation is that humans will round a digit when they are uncertain or unconfident about the exact numerical value of that digit. In such cases rounding implicitly signals the lack of precision or accuracy. For example, in the handbook for real estate appraisers, *The Appraisal of Real Estate*, the Appraisal Institute (2008) states that:

> Customarily appraisal conclusions are rounded to reflect the lack of precision associated with value opinions. The more confidence the appraiser has in the opinion, the less need there is for rounding.

Analysts' earnings forecasts are similar to real estate appraisals in that the analyst faces uncertainty when forecasting future earnings. If an analyst lacks confidence that the precision of the forecast holds to the penny digit, then his or her choice is either to: (1) round the forecast to the level of precision with which the analyst feels comfortable (e.g., the nearest dime or quarter) or (2) arbitrarily assign a number to the penny location. Note that decision (1) will automatically lead to a rounded forecast. Decision (2) could also lead to a rounded forecast if the analyst is subject to the behavioral bias of "heaping" when arbitrarily assigning a number.

Herrmann and Thomas (2005) provide evidence that rounded forecasts are less accurate than other forecasts. They suggest that the reason for the lower accuracy is that rounding analysts are less informed/have less information than other analysts. Their tests focus on *analyst characteristics* and they investigate whether rounding analysts work for smaller brokerage houses, have poorer past accuracy, are following more firms from more industries, forecast less frequently, have longer forecast horizons, and have been following the firm for a shorter period of time.

In this paper we adopt a different but complementary approach to Herrmann and Thomas (2005). Specifically, we argue that analysts can *choose* to be less informed about a particular stock and this choice affects how certain they feel about their forecasts, and as a consequence, their decision to round. In other words, analysts can rationally decide not to provide a forecast precise to the penny even when the information to help them do so is readily available.[2] This is because exerting effort to provide more precise forecasts is costly to analysts.[3] Analysts have limited time and so will rationally focus their forecasting efforts on firms for which the benefits of doing so are the highest. Our tests therefore focus on whether the *followed firm attributes* impact analysts' decision to round.

---

[1] In the U.S., the convention is to forecast EPS in dollars and cents. Therefore, we assume that an analyst is more likely to have engaged in rounding when the forecast has a 0 or 5 in the penny location.

[2] For example, an analyst following IBM may know that reading the 10K and learning more about the industry will improve his confidence and his ability to provide a precise EPS forecast. However, even with this information readily available, due to the opportunity cost of the time and effort required to read and understand the information, the analyst may choose not to become more informed (e.g., because he would like to become the lead analyst for Google and so is focusing his time and effort on Google).

[3] Placing a number other than 0 or 5 in the penny location of a forecast does not physically require more effort on the part of the analyst. The point is that when an analyst exerts less effort in forecasting, he will be less confident and be more uncertain about his forecast. This lack of confidence and greater uncertainty results in an increased likelihood of rounding.

Our first test examines an intuitive reason for analysts to round. As earnings per share increases from one digit (e.g., 0.05) to two (0.55), three (1.55), or four digits (15.55), the economic importance of the penny digit to investors in valuing the firm declines. Hence, an analyst is less likely to exert effort to obtain "to-the-penny" precise information to forecast larger EPS with four digits than smaller EPS with fewer digits. Furthermore, other things being equal, it is also more difficult and requires more effort for an analyst to forecast the penny digit accurately for four-digit EPS than others with fewer digits.[4] As a result, we would expect the uncertainty that an analyst faces in determining the penny digit of his forecast to increase with the magnitude of the forecast. This will also lead an analyst to round more for EPS forecasts with larger magnitude.

We show that about 34 percent of forecasts are rounded for stocks where forecast EPS is less than \$1, and this increases to 49 percent for stocks where forecast EPS is between \$1 and \$10 and is over 60 percent for stocks with EPS forecasts over \$10.00. In addition, we find that the incidence of the number 5 increases to around 20 percent for EPS forecasts up to \$1.00 and then remains steadily at 20 percent for higher levels of EPS. These findings suggest that the high prevalence of rounding observed by Herrmann and Thomas (2005) is at least partly due to analysts rationally choosing to round as the economic significance of the penny location declines.

Our second and third tests examine whether analysts' compensation incentives impact the decision to round. We expect analysts to put more effort into providing an accurate and informative forecast when there is more monetary benefit for them from doing so. Part of an analyst's job is to provide research to clients that will generate interest in the stock and encourage trading through the brokerage division (Irvine 2000; and Jackson 2005). More trading activity results in greater brokerage fees for the brokerage division and more bonus compensation for the analysts (Groysberg et al. 2008). Prior research suggests that brokerage fees are positively correlated with trading volume, stock price volatility, institutional holdings, and growth opportunities (e.g., Frankel et al. 2006). We predict that analysts will round more in firms that generate less brokerage fees since there is less benefit to exerting effort to obtain precise information. Our results are consistent with this prediction.

Our third test examines whether there is a relation between rounding and external financing. Corporate financing is an important source of revenues for many investment banks (Lin and McNichols 1998; Michaely and Womack 1999; Bradshaw et al. 2006). A firm that is followed by analysts and is seeking to raise more external financing is likely to be viewed by the investment bank as having greater revenue-generating potential. In helping their employers attract and compete for underwriting business, analysts are likely to exert more effort in forecasting earnings for potential investment banking clients. We therefore predict that analysts will round less when forecasting earnings for firms raising more external financing. Our results are consistent with this prediction.

Our fourth test examines the impact of firm complexity on analysts' tendency to round. Large companies and companies with more complicated business models require the analyst to acquire more information and exert more effort in understanding the business. All else equal, this would result in a greater propensity to round. However, the demand for analysts' services by investors is likely to be higher for larger, more complex firms. This could result in greater analyst effort, and so, in less rounding. Our results indicate that rounding increases both with size and the number of

---

[4] For example, when earnings equal \$1,543 and the number of shares is 100, then EPS is four digits (15.43). If the number of shares outstanding increases to 10,000, then EPS is two digits (0.15). The penny digit of the forecast is accurate to the nearest dollar of total earnings for the four-digit forecast but to the nearest hundred dollars for the two-digit forecast. It is likely more difficult and therefore requires more effort for an analyst to forecast the value of earnings to be \$1,543 than to be around \$1,500.

business segments. These results suggest that, on balance, analysts are more likely to round when following larger, more complex firms.

Our findings complement and build on Herrmann and Thomas (2005). In their research they determine whether rounding analysts are less informed than other analysts following the same firm. Thus, their approach controls for firm characteristics. In contrast, we argue that *firm characteristics* affect analyst incentives and their tendency to round. We find that: (1) the explanatory power of firm characteristics is about three times greater than that of analyst characteristics; and (2) firm characteristics have significant incremental explanatory power over analyst characteristics in explaining rounding.

Our final test examines one implication of rounding. Prior research shows that earnings response coefficients are biased down when there is more noise in proxies for the market's expectation of earnings due to a classic "errors in variables" problem (Imhoff and Lobo 1992; Burgstahler and Chuck 2010; Kim 2011). If investors understand that rounded forecasts contain more noise, then they should place a lower weight on these forecasts in forming their expectations. As a result, rounded forecasts will be a noisier proxy of the market's expectation and will have lower earnings response coefficients than other forecasts. Our results are consistent with this prediction.

Our results also show that rounded forecasts are not only less accurate, but also more optimistically biased than other forecasts. Hence, we also examine whether investors adjust for this optimistic bias in their expectations of earnings. We find that, on average, rounded forecasts have a small but significantly lower announcement return than other forecasts, suggesting that investors may not fully adjust for the optimistic bias associated with rounded forecasts.

The next section provides a discussion of prior research. Section III develops our predictions. In Section IV we provide our sample selection. Section V investigates the determinants of rounding and investor response to rounded forecasts. Section VI concludes.

II. PRIOR RESEARCH

Several avenues of research in accounting and finance have examined whether investors, managers, or analysts focus or herd to specific numbers. For example, Carslaw (1988) finds that there are more zeros and fewer nines than would be expected by chance in the second-from-left-most digit in reported earnings for New Zealand firms. Thomas (1989) shows similar unusual patterns for reported earnings for U.S. firms covered in the Compustat database. Furthermore, he documents a greater propensity of zeros and fives in the third digit of EPS numbers for the sample. Das and Zhang (2003) confirm Thomas's (1989) findings and extend the research by showing that the unusual frequency of rounded EPS reflects managers' incentive to round up EPS to meet analysts' forecasts, report positive profits, and sustain recent performance. A more recent study by Bamber et al. (2010) identifies rounding patterns in managers' EPS forecasts. Their findings suggest that nearly half of managers' annual EPS forecasts end in nickel intervals. They argue that managers' nickel forecasts appear to reflect managers' efforts to protect proprietary information and are due to self-serving opportunism.

The finance literature presents similar rounding phenomena in the distribution of stock prices on the U.S. equity markets (e.g., Osborne 1962; Niederhoffer 1965, 1966; Harris 1991; Christie and Schultz 1994; Godek 1996; Grossman et al. 1997; Cooney et al. 2003; Johnson et al. 2008). Harris (1991) shows price clustering increases with price level and volatility and decreases with capitalization and transaction frequency. These results are subsequently confirmed and other implications are investigated concerning the desirability of certain numbers in international stock markets (e.g., Aitken et al. 1996; Brown et al. 2002; Ahn et al. 2005; Sonnemans 2006; Brown and Mitchell 2008).

The paper closest to ours is Herrmann and Thomas (2005), which documents a high prevalence of rounding in analyst annual EPS forecasts. They argue that rounding will occur when an analyst is less informed and so rounded forecasts will be less accurate. They use prior research examining analyst characteristics that are correlated with accuracy to predict which analysts are more likely to round.[5] They compare rounding analysts to non-rounding analysts following the same firm and, consistent with their predictions, document that rounding analysts: work for smaller brokerage firms; have poorer past accuracy; update their forecasts less frequently; have longer forecast horizon; and follow more firms from more industries. However, their research also raises questions as to whether analysts' characteristics are a complete explanation for rounding. First, they note in the text that rounding is more common in transportation, public utilities, and energy (Herrmann and Thomas 2005, 820). It is unclear why less-informed analysts would gravitate to these industries. Second, Herrmann and Thomas (2005) document that rounding analysts have been following firms for a longer period of time. Again, it is unclear why an analyst would become less informed, the longer he/she follows a firm. Herrmann and Thomas (2005) recognize these concerns and suggest that future research probe these issues in more detail.

In our paper we conjecture that analysts rationally trade off the benefits and costs of providing informative and precise forecasts, and that these trade-offs depend on *firm characteristics*. In taking this perspective we are able to generate predictions that are not implications of an *analyst characteristics* perspective. For example, we predict that rounding will increase with the level of EPS. We can see no reason why analyst characteristics would vary with the level of EPS. In addition, if lack of expertise and information were the main drivers of rounding, then one might expect rounding to occur more frequently in difficult-to-forecast stocks such as those with high-growth expectations and those that have high earnings and stock price volatility. In contrast, we argue that although these stocks are difficult to forecast, the demand from investors for more information is greater. Thus, we predict less rounding in these stocks.

Our paper also contributes to prior research that analyzes the informativeness of analyst research reports. Prior research has used the stock market reaction to analyst reports as a proxy for the informativeness of the report (see Frankel et al. 2006). However, the use of this proxy is complicated by a number of factors.[6] In contrast, we conjecture that rounded forecasts can be used as an easy-to-observe proxy for a "noisier" forecast. We therefore do not rely on the stock market response to determine the "informativeness" of the EPS forecast. Instead, we can examine directly how investors respond to a less informative report, as proxied by a rounded forecast, as an implication of our findings.

III. PREDICTIONS

We predict that rounding will be influenced by firm characteristics. These characteristics include the level of EPS and the value of the firm for creating brokerage and investment banking business, as well as the complexity of the business. Herrman and Thomas (2005) suggest that analyst characteristics influence rounding and so we include predictions for these variables as well. Finally, we provide our predictions relating to earnings response coefficients.

---

[5] The link between forecast accuracy and analyst characteristics has been investigated by Mikhail et al. (1999), Clement (1999), Jacob et al. (1999), Brown (2001), and Clement and Tse (2003).

[6] First, the researcher must assume that markets are efficient and that investors do not ignore or under- or overreact to analyst reports. Second, there are endogeneity issues that need to be addressed since some of the determinants of the stock market reaction to the report are also likely to be affected by whether analyst reports are informative (O'Brien and Bhushan 1990; Alford and Berger 1999; Frankel et al. 2006).

The Level of EPS (Predicted Sign: +)

The convention in the U.S. is for analysts to forecast EPS to the nearest penny. This contrasts with forecasts in the U.K. and Australia that regularly report fraction of a penny forecasts. Thus, in the U.S., an analyst forecasting EPS that is less than $1 need only forecast two digits (i.e., 0.xx), while a U.S. analyst forecasting EPS over $1 will forecasts three (x.xx) or even four digits (xx.xx). *Ceteris paribus*, forecasting EPS to four digits requires more effort than forecasting EPS to two digits. In addition, as the level of EPS increases, the economic importance of the penny digit declines, and so the demand for "to the penny precision" by investors is likely to decline. Analysts are likely to round more as the magnitude of EPS increases either because they round to the digit with which they are most confident, or because, when arbitrarily assigning a value to the digit they engage in the behavioral bias of heaping. A similar logic applies to firms with negative earnings. As the level of loss increases (i.e., earnings becomes more negative), analysts are likely engage in more rounding. Therefore we predict that rounding will increase with the absolute value of EPS.[7]

Note that although it is intuitive to expect rounding to increase with the absolute value of EPS, such a finding is not mechanical or predetermined. Cheong and Thomas (2011) show that unscaled forecast errors do not vary with the level of stock price. Given that the level of stock price and EPS are highly correlated, the results suggest that analysts may care about the accuracy of the penny position irrespective of the level of EPS. In addition, we show that actual reported EPS is not rounded as the level of EPS increases. Thus, it is an empirical question as to whether and to what extent rounding varies with the level of EPS.

Investor Recognition and Trading Commissions

We expect analysts to exert more forecasting effort when doing so potentially increases their compensation. If analyst compensation is positively related to trading commissions, then we expect analysts to exert more forecasting effort in firms that generate greater brokerage fees. We contend that an analyst is more likely to round when he or she is exerting less effort and so is less confident about the forecast. Therefore, we expect more rounding in firms that generate less brokerage business. Below we provide our proxies for brokerage fees.

Trading Volume (Predicted Sign: –)

A stock that has a high trading volume offers greater opportunities for trades to pass through the brokerage division (Jackson 2005). Analysts who provide more informative research are likely to generate more trading business, and this can benefit the analyst. In addition, trading volume can also reflect greater disagreement among investors about the value of the company and, hence, encourage information search (e.g., Beaver 1968; Karpoff 1986; Harris and Raviv 1993; Kandel and Pearson 1995; Kim and Verrecchia 1997). In contrast, low trading volume offers fewer brokerage fee opportunities, and so analysts are likely to exert less effort in forecasting. This lack of effort will result in greater uncertainty concerning the penny digit and will increase the likelihood that the analyst will round.[8]

---

[7] Note that our prediction is similar to Harris (1991) who predicts that stock prices will exhibit more clustering around zero as the price level increases. However, our prediction relates to analyst incentives while Harris's (1991) prediction relates to incentives of traders and exchange regulations.

[8] Herrmann and Thomas (2005) find that more regulated, slower growth industries have more rounded forecasts. They suggest that analysts might provide less effort and commit fewer resources toward these firms because these industries likely generate less trading revenue for brokerage firms. The trading revenue argument is proposed as an untested conjecture in Herrmann and Thomas (2005). We test the hypothesis formally in this paper.

Return Variance (Predicted Sign: –)

If there is more uncertainty about a firm's future cash flows, then the stock is likely to have greater return volatility. Higher volatility presents more opportunities for traders to gain from information acquisition and so increases the demand for informative analyst research (e.g., Frankel et al. 2006). In contrast, a stock that has low return volatility and stable earnings offers fewer opportunities to gain from trade and so decreases the demand for informative forecasts. We therefore expect rounding to occur more frequently in firms with low return variance. Our prediction contrasts from what one would expect under a purely "analysts' lack of information" perspective on rounding. Holding everything else constant, one would expect less volatile stock to be easier to predict and, hence, would require less rounding.

Institutional Ownership (Predicted Sign: –)

The usefulness of analyst research for institutional investors is an important factor in determining whether analysts are nominated for *Institutional Investors*' "All American Research Team." Being viewed by institutions as the lead analyst in a particular industry can have significant compensation benefits (Groysberg et al. 2008). This suggests that an analyst is likely to exert more effort in valuing companies and forecasting earnings in firms with greater institutional holdings. In addition, since many institutions trade frequently, institutions can reward analysts for informative reports by trading through the brokerage division. In contrast, a stock with little institutional representation is likely to have fewer such side-benefits, and so an analyst is likely to put in less effort to produce an informative report and forecast, and more likely to round.

Growth Opportunities: Book-to-Market and Earnings-to-Price (Predicted Sign: +)

Frankel et al. (2006) point out that the effect of growth opportunities on informative reports depends on several factors. The value of growth firms is determined to a greater extent by future profitability relative to current profitability. Thus, providing more informative reports requires the analyst to exert effort and incur higher information-gathering costs to determine potential future opportunities. However, investors are also more interested in growth companies because of the greater potential gains, and this creates an increased demand for analyst guidance. In contrast, the earnings of low-growth firms are likely to be easier to forecast and to require less information acquisition on the part of the analyst, but the demand for informative reports is also likely to be lower. On balance, low-growth stocks are more likely to have lower investor interest and are less likely to raise financing. Therefore, low-growth firms are likely to be less lucrative for the employers of analysts, and so we expect less forecasting effort. As a consequence, we predict analysts are more likely to round in these firms. Our proxies for growth opportunities are *book-to-market* and *earnings-to-price*. We expect firms with fewer growth opportunities to have high values of both ratios.

Investment Banking Business Opportunities

External Financing (Predicted Sign: –)

Firms that are raising financing frequently select the investment bank that has a favorable analyst following the firm to underwrite the deal (Lin and McNichols 1998; Michaely and Womack 1999; Dechow et al. 2000; Bradshaw et al. 2006). Understanding this relation, an analyst who is covering a firm that is likely to need financing is likely to exert more effort in forecasting. By having greater knowledge of the firm, the analyst will increase the corporate finance division's ability to attract the firm as a client. We therefore predict that analysts are less likely to round their forecasts for firms that are raising financing. Following Bradshaw et al. (2006), we use the

Statement of Cash Flows to determine the amount of cash raised from debt and equity financing. We calculate *EXFIN* as the net amount of cash flow received from financing activities scaled by the market value of common equity of the current fiscal year.

Business Complexity

Firm Size (Predicted Sign: ?)

Larger firms are more complex than small firms, making them more difficult to analyze and value. In addition, if an analyst does provide an informative report, then this information is likely to be quickly dispelled among market participants and not necessarily captured by the analysts' brokerage division. The impact of these factors will increase the likelihood of observing rounding in forecasts for large firms. However, larger firms are also likely to have other sources of information, such as news reports and management voluntary disclosures, that potentially reduce the effort analysts must incur to forecast earnings. These factors would reduce the likelihood of observing rounding in large firms. Note also that size can proxy for many different things (e.g., it could also be correlated with brokerage fees). Therefore, we include *SIZE* in our tests, but we do not sign our prediction for this variable.

Number of Business Segments (Predicted Sign: +)

Companies with complicated business models require more effort to understand and therefore impose more costs on analysts. Effort-averse analysts, when facing these higher costs, could refrain from collecting information. This could lead to a positive association between business complexity and rounding. However, multiple-segment firms tend to be large firms. Investors could demand more informative forecasts for these firms. This could give analysts more incentive to acquire information and therefore lead to less rounding. We therefore predict that controlling for firm size, firms with more business segments will have more rounded forecasts.

Analyst Characteristics

Herrmann and Thomas (2005) examine the influence of analyst characteristics on analyst decisions to round EPS forecasts. Specifically, they investigate whether analysts are more likely to round when they have lower past accuracy, work for smaller brokerage firms, forecast less frequently, have less firm experience, have more stale forecasts, or when they follow more firms or more industries. For completeness and comparability, we include these analyst characteristics variables in our tests. Our definitions of variables are the same as in Herrmann and Thomas (2005). The detailed variable definitions are provided in Appendix A.

Rounding and Earnings Response Coefficients

Our final prediction tests one implication of rounding. If rounding proxies for analysts exerting less effort, and in turn, having less accurate forecasts, then rounded EPS forecasts will be a poorer proxy of the market's expectation of earnings than non-rounded forecasts. If this is the case, then earnings surprises (actual EPS – forecast EPS) based on rounded forecasts will contain more error than non-rounded forecasts of EPS. We therefore predict that earnings response coefficients will be lower for rounded forecasts due to the greater error in variables problem with these forecasts.

IV. SAMPLE

We obtain financial statement data from Compustat and stock returns from CRSP. We obtain analyst forecasts from I/B/E/S for the period 1984 to 2009. We use the *unadjusted* detail database to

EXHIBIT 1

Earnings Announcement

avoid the retroactive stock split rounding effect as described in Baber and Kang (2002) and Payne and Thomas (2003). For our empirical tests, we obtain the most recent *annual* EPS forecasts. This is the forecast for each available analyst, made closest to the corresponding annual earnings announcement date. We allow the "most recent" forecast for a specific analyst to be made up to one year prior to the earnings release date. See Exhibit 1 for a timeline.

We collect the actual EPS from I/B/E/S to ensure consistency with the forecasts in the treatment of nonrecurring items. *Accuracy* is calculated as the absolute value of *Forecast – Actual EPS*. When we calculate *Accuracy* we adjust the forecast for splits between the time that the forecast was made and the release of actual EPS. We do this so that both actual EPS and forecast EPS are measured on the same basis. We scale the forecast error in two ways. We first scale the forecast error by price to help make it comparable across firms. We also scale the forecast error by the absolute value of actual EPS. We scale observations wherein the absolute value of actual EPS is less than 3 cents by 3 to control for the effect of extreme outliers.[9] We also examine forecast *bias* since analysts tend to be optimistic and, therefore, accuracy is likely to be correlated with bias. In addition, it is interesting from a descriptive perspective to determine the extent to which rounded forecasts are biased.

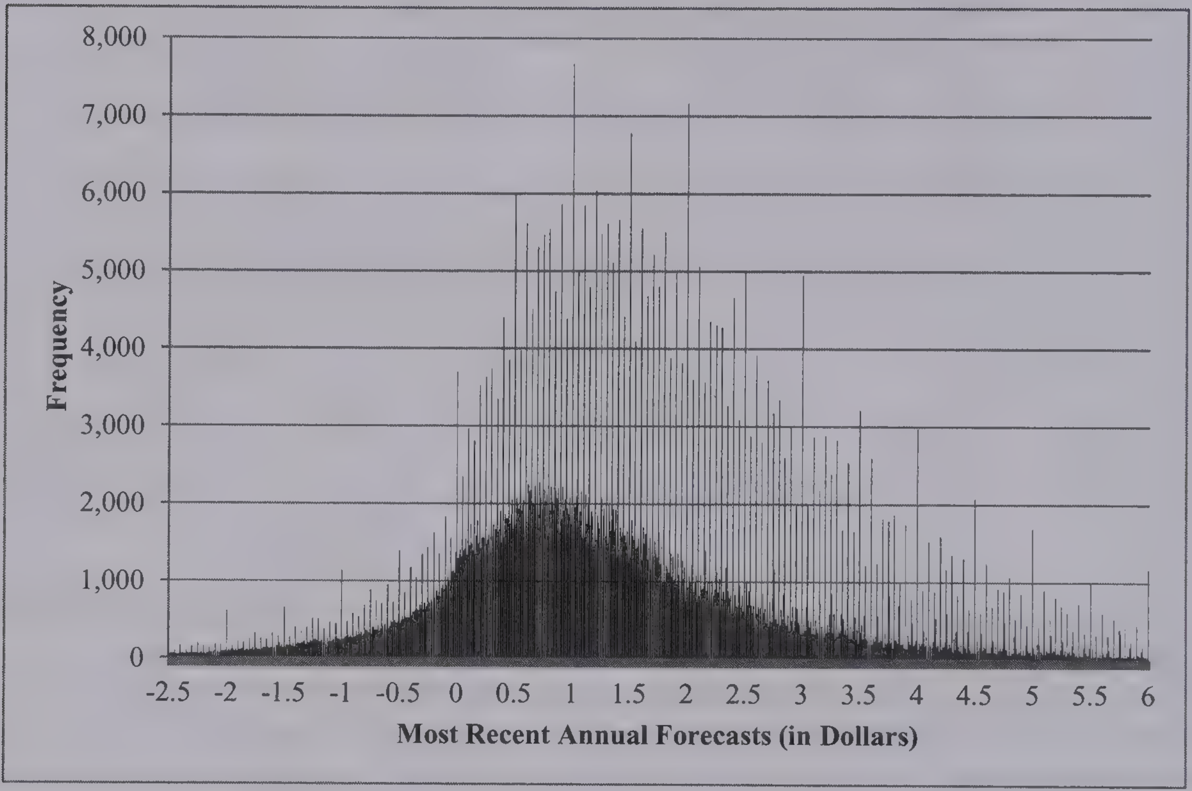
V. RESULTS

Our results are presented in four sections. We present descriptive evidence relating to rounding in the earnings forecast distribution and details on how rounding changes with the level of the EPS forecast. We next provide our formal tests examining the relation between firm characteristics and rounding using the analyst forecast as the variable of analysis. We then present a similar analysis of the data at the firm level. The final section provides our tests of the relation between earnings response coefficients and rounding.

---

[9] Excluding all observations with actual EPS less than 3 cents instead of winsorizing them does not change the conclusions.

FIGURE 1
Distributions of Analyst EPS Forecasts



This figure plots the distribution of the most recent EPS forecasts for each firm-analyst-year observation. The sample includes 809,129 observations from 1984 to 2009, among which 46.30 percent are rounded to the nearest 5 cents.

Descriptive Evidence on Rounding and Its Relation to the Level of EPS

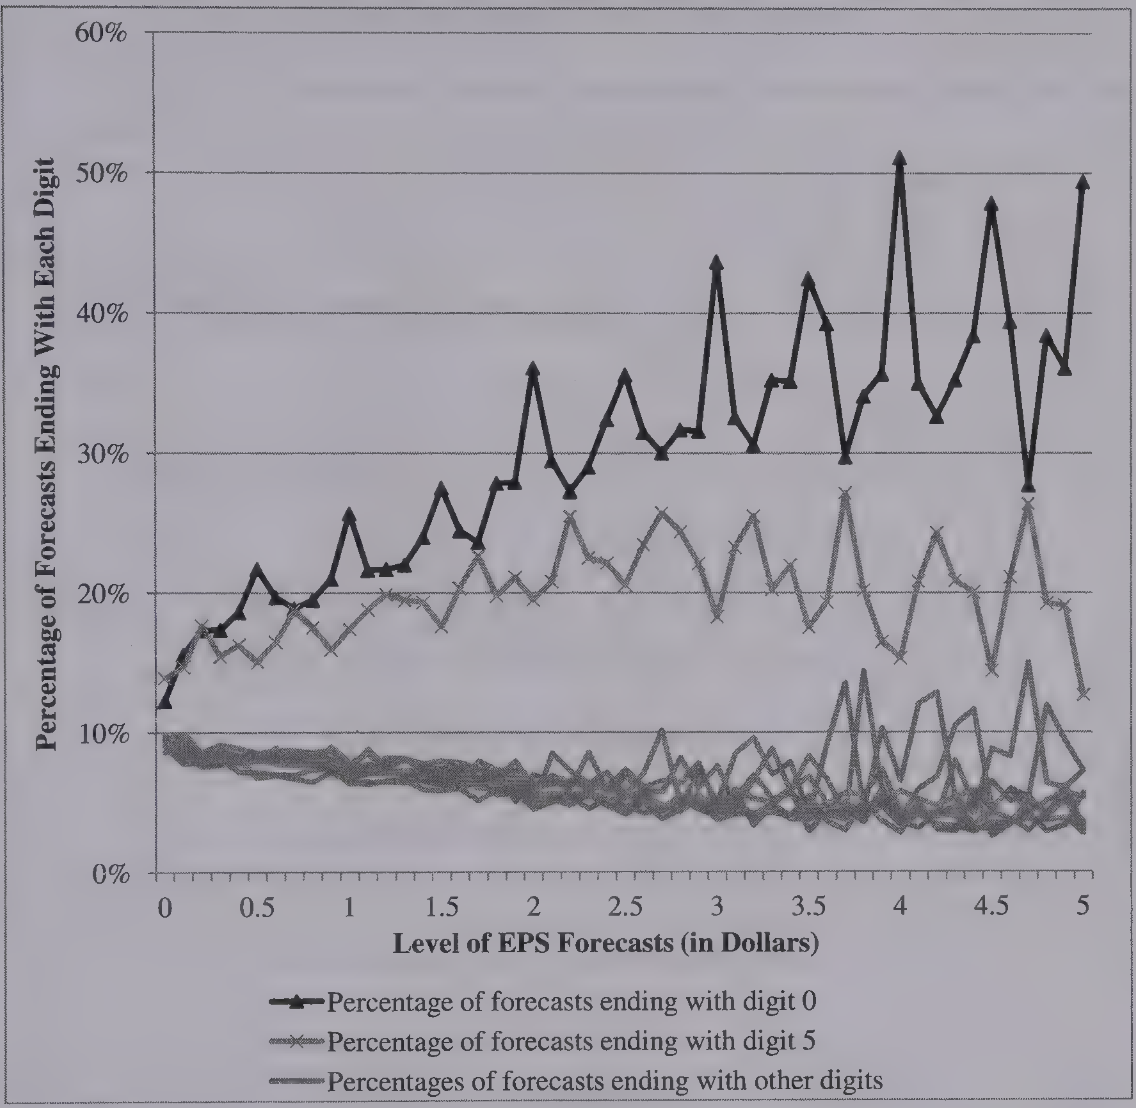
Figure 1 provides the distribution of analyst EPS forecasts. There is clearly a greater frequency of forecasts that are rounded to the nearest 50 cents ($1, $1.50, $2, etc.), then to the nearest 10 cents ($1.10, $1.20, $1.30, etc.), and finally to the nearest five cents (e.g., .65, .75 cents). Among the 809,129 most recent annual EPS forecasts, 46.30 percent are rounded to 0 or 5.

Figure 2 examines the proportion of forecasts ending with each digit as the level of EPS increases. The horizontal axis reports the level of EPS in 10-cent intervals (0.10 to 0.20, etc.) and the vertical axis reports the proportion of forecasts that ends with each specific digit. Figure 2 shows that as the level of EPS increases to $5.00, the proportion of forecasts that end with zero increases from just above 10 percent to around 40 percent. The figure also indicates that the proportion of EPS forecasts ending with a five increases from around 15 percent but then steadies out at about 20 percent after forecast EPS is over $1.00. Thus analysts appear to round more to 0 than to 5 as the level of EPS increases. The figure shows that the proportions of forecasts ending with digits 1 through 4 or 6 through 9 tend to decline below 10 percent as the level of EPS increases.

Figure 3, Panel A is similar to Figure 2 except that it combines forecasts that end with a zero or a five and plots the combined proportion as the level of forecast EPS increases. We also plot the proportion of actual EPS that have a 0 or 5 in the penny digit to compare the relative proportions. As expected, the percentage of rounded forecasts increases systematically with the magnitude of EPS forecasts. In contrast, the percentage of actual EPS that ends with a 0 or 5 in the penny digit stays at about 20 percent across the whole range that we examine. Panel B of Figure 3 reports the extent of rounding for negative EPS stocks.

FIGURE 2

Percentage of Forecasts Ending with Zero, Five, versus Other Digits



This figure plots the percentage of forecasts ending with zero, five, and other digits for forecasts of different magnitudes. We place analysts' forecasts into bins with width of 10 cents. For example, bin $0.0 includes forecasts in the range of [0,0.10), bin $0.10 includes forecasts in the range of [0.10,0.20) etc.

The results show a similar, although somewhat weaker, increasing trend of rounding in EPS forecasts as the absolute value of the forecasts increases.

Table 1 provides a more detailed analysis of analyst EPS forecasts ending with each digit. The digits are ranked from the highest to the lowest percentage of the distribution. The results indicate that zeros are most common (25.95 percent), followed by 5 (18.66 percent). For other digits, consistent with analysts applying the "round half to even rule," there are a greater frequency of forecasts that end with an even number (29.99 percent) than forecasts that end with an odd number (25.40 percent).[10] The next most

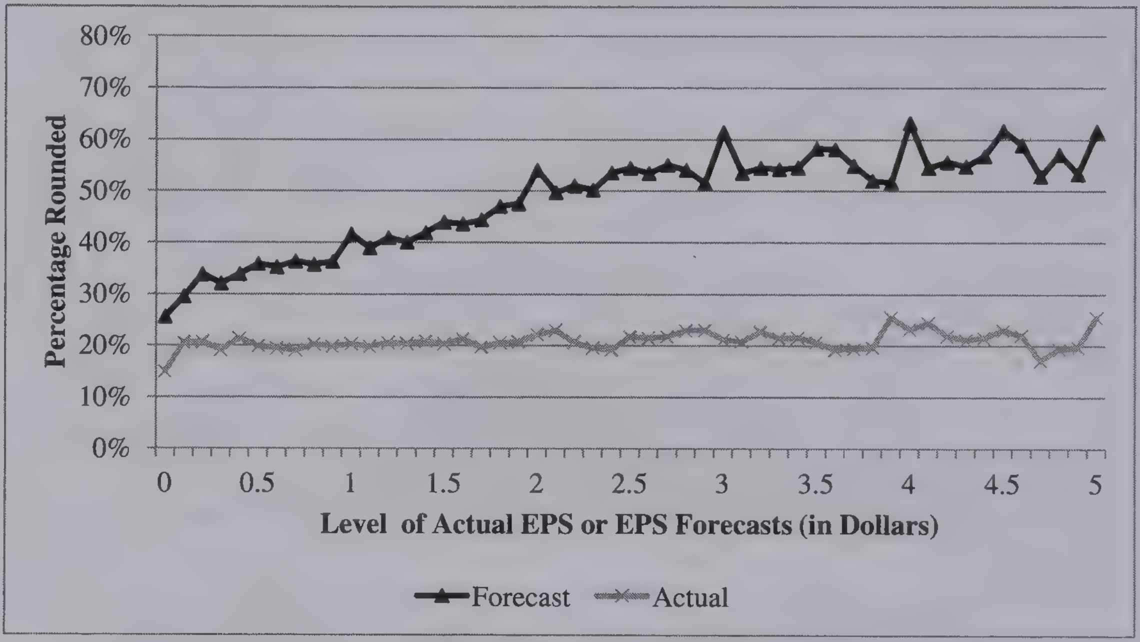
---

[10] The "round half to even" rule is a tie-breaking rule when the digit to be rounded off is 5. This method is commonly used in bookkeeping and involves analyzing the digit that is affected by the rounding. If the digit is odd, then the number is rounded up to an even number; if the digit is even, then the number is rounded down to the even number. For example, 3.5 is rounded up to 4, 2.5 is rounded down to 2.

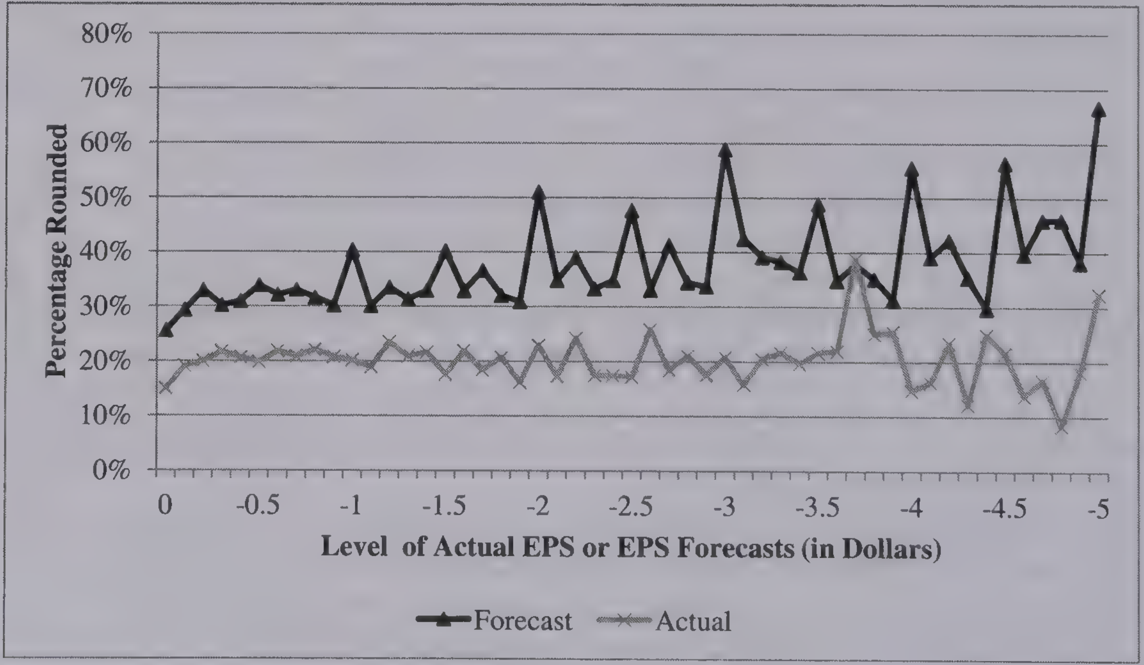
FIGURE 3

The Relation between Rounding (the Penny Digit Being a Zero or Five) and the Level of Actual Reported EPS and Forecast EPS

Panel A: Percentage of Rounded Forecasts for Positive Forecasts



Panel B: Percentage of Rounded Forecasts for Negative Forecasts



This table plots the percentage of rounded (the penny digit being a zero or five) actual EPS or forecast EPS for different levels of EPS. We put observations between −\$5 and \$5 into 101 bins each with an interval of \$0.1, for example, bin labeled \$0.0 includes those forecasts in the range of [\$0, \$0.01), bin labeled −\$0.1 includes those in [−\$0.1, 0), and bin labeled \$0.1 contains those in [0, \$0.1).

The Frequency, Accuracy, and Bias of Each Cent Digit of Analyst EPS Forecasts

Panel A: Frequency, Forecast Bias, and Forecast Accuracy for Analyst EPS Forecasts Ending with Each Digit (Forecast Error is defined as 100 × (Forecast − Actual)/Price; Forecast Accuracy is defined as 100 × |Forecast − Actual|/Price)

Cent Digit	n	Percentage of Distribution	Mean Forecast Error (Bias)	Mean Absolute Forecast Error (Accuracy)	Bias/Accuracy
0	198,385	25.95%	1.439	2.246	0.64
5	142,652	18.66%	1.189	1.945	0.61
Other even digits					
6	58,918	7.71%	0.873	1.633	0.53
4	57,803	7.56%	0.883	1.662	0.53
2	57,460	7.52%	0.971	1.748	0.56
8	55,050	7.20%	0.901	1.679	0.54
Combined	229,231	29.99%	0.907	1.680	0.54
Other odd digits					
3	50,757	6.64%	0.963	1.764	0.55
7	49,949	6.53%	0.932	1.755	0.53
1	47,432	6.20%	1.186	2.002	0.59
9	46,103	6.03%	0.988	1.843	0.54
Combined	194,241	25.40%	1.015	1.839	0.55

Panel B: Frequency, Forecast Bias, and Forecast Accuracy for Analyst EPS Forecasts Ending with Each Digit (Forecast Error is defined as (Forecast − Actual)/max(0.03,|Actual|); Forecast Accuracy is defined as |Forecast − Actual|/max(0.03,|Actual|)

Cent Digit	n	Percentage of Distribution	Mean Forecast Error (Bias)	Mean Absolute Forecast Error (Accuracy)	Bias/Accuracy
0	198,385	25.95%	0.173	0.287	0.60
5	142,652	18.66%	0.146	0.259	0.56
Other even digits:					
6	58,918	7.71%	0.092	0.217	0.42
4	57,803	7.56%	0.088	0.222	0.40
2	57,460	7.52%	0.086	0.222	0.38
8	55,050	7.20%	0.084	0.213	0.40
Combined	229,231	29.99%	0.088	0.218	0.40
Other odd digits:					
3	50,757	6.64%	0.081	0.225	0.36
7	49,949	6.53%	0.080	0.217	0.37
1	47,432	6.20%	0.085	0.235	0.36
9	46,103	6.03%	0.088	0.223	0.40
Combined	194,241	25.40%	0.083	0.225	0.37

common numbers are the even numbers around 5, that is, 6 and 4. The least-reported digits are 1 and 9 that are on either side of 0. The low frequency of 1 and 9 is consistent with these being the first numbers to get rounded to 0 as the level of EPS increases.

Consistent with Herrmann and Thomas (2005), the results in Table 1, Panel A indicate that forecasts ending with 0 and 5 are less accurate than other forecasts. Herrmann and Thomas (2005) do not investigate the bias in forecasts, but our results suggest that bias plays a role in explaining the relative inaccuracy of rounded forecasts.[11] We find that 0 and 5 forecasts are more optimistically biased than other forecasts. In addition, the ratio of bias to accuracy is approximately 61–64 percent for rounded forecasts. In contrast, this ratio is around 55 percent for other numbers. Therefore, when analysts face uncertainty and decide to round, they tend to round *up*. Why they should round up is not immediately obvious. One possible explanation is linked to our tests reported later in the paper. It is a well-known empirical regularity that analyst forecasts tend to be "walked down" as the earnings announcement approaches (e.g., Richardson et al. 2004). If analysts round more in stocks that are of little investor interest, then they may also be less likely to update their forecasts as new information becomes available. Consistent with this explanation, we find that rounded forecasts tend to be staler than non-rounded forecasts.[12] Panel B of Table 1 presents similar results for forecast errors scaled by actual EPS.

Table 2 provides details concerning the extent of rounding for different parts of the forecast EPS distribution. Panel A reveals that about 32 percent of negative forecasts are rounded. For positive EPS forecasts under $1.00, approximately 34 percent of the forecasts are rounded. For stocks between $1.00 and $10.00 approximately 49 percent are rounded, and for the few stocks with EPS forecasts greater than $10 but less than $100, approximately 60 percent are rounded. Rounding increases to 95 percent for the very few stocks with forecast EPS over $1,000. Panel A also shows that rounded forecasts are less accurate in categories where EPS forecasts are less than $10.00. For high EPS stock (over $10.00), rounding no longer appears to reflect a lack of uncertainty since rounded forecasts are close to or somewhat more accurate than non-rounded forecasts. This could be because, for high EPS stock, rounding to the nearest penny has very little impact on overall precision, or because rounding is done purely to provide a simpler number that is easier to communicate. Panel B provides results concerning bias and mirrors the accuracy results reported in Panel A.

In summary, Herrmann and Thomas (2005) hypothesize that rounding is due to analysts lacking information to accurately forecast EPS. The results in this section provide an additional and complementary explanation. Our results indicate that rounding increases with the level of EPS. As EPS increases, the penny digit of the forecast is of less economic significance and, by rounding, analysts indicate (either intentionally or subliminally) that their forecasts are not precise "to the penny." In addition, as EPS increases, analysts could round to produce a number that is easier or simpler to communicate. Finally, our results suggest that rounded forecasts are more optimistically biased than other forecasts. When analysts round, they tend to round up.

Analyst-Level Analysis

We next investigate the relation between rounded forecasts and our firm-specific determinants. We first estimate the following logistic model:

---

[11] In a related study, Zhou (2010) documents an optimistic bias associated with "nickel forecasts." Zhou (2010) does not investigate firm-specific determinants of rounding.

[12] In unreported tests we find that rounded forecasts are more biased than non-rounded forecasts even after controlling for forecast horizon. Therefore, the walk-down effect is a partial, but not complete, explanation for the bias.

TABLE 2

Mean Forecast Accuracy and Bias for Rounded versus Other Forecasts

Panel A: Forecast Accuracy = 100 × |Forecast − Actual|/Price

Group	n	Percent Rounded	Rounded	Other	Difference
(−∞,0)	88,755	32.26%	8.266	5.663	2.603***
[0, 1)	199,918	34.15%	2.832	1.654	1.178***
[1, 10)	469,899	49.36%	1.163	0.825	0.338***
[10, 100)	5,750	60.44%	1.529	2.429	−0.900***
[100, 1,000)	149	90.60%	1.598	5.767	−4.169
[1,000, ∞)	38	94.74%	0.555	1.739	−1.184***

Panel B: Forecast Bias = 100 × (Forecast − Actual)/Price

Group	n	Percent Rounded	Rounded	Other	Difference
(−∞,0)	88,755	32.26%	5.814	3.428	2.386***
[0, 1)	199,918	34.15%	2.052	0.920	1.132***
[1, 10)	469,899	49.36%	0.588	0.350	0.239***
[10, 100)	5,750	60.44%	0.810	1.639	−0.830***
[100, 1,000)	149	90.60%	1.456	5.676	−4.220
[1,000, ∞)	38	94.74%	0.017	−1.739	1.756***

*** Indicates significance at the 1 percent level.

This table compares the forecast accuracy and forecast bias for rounded versus other forecasts at different levels. Rounded forecasts are forecasts that end with a 0 or 5 in the penny digit.

$$\begin{aligned} Prob(ROUND_{i,j,t} = 1) = F(&\beta_0 + \beta_1 ALAGEPS_{i,t} + \beta_2 VOLATILITY_{i,j,t} + \beta_3 VOLUME_{i,j,t} \\ &+ \beta_4 INST\_HOLD_{i,j,t} + \beta_5 BM_{i,j,t} + \beta_6 EP_{i,j,t} + \beta_7 EXFIN_{i,t} \\ &+ \beta_8 SIZE_{i,j,t} + \beta_9 NSEG_{j,t} + \varepsilon_{i,j,t}), \end{aligned} \tag{1}$$

where $F(\beta'X) = e^{\beta'X}/(1 + e^{\beta'X})$.

$ROUND_{i,j,t}$ = 1 if analyst *i*'s most recent forecast of EPS for firm *j*'s year *t* is a rounded forecast, and 0 otherwise;

$ALAGEPS_{i,t}$ = absolute value of year *t*–1 actual EPS of firm *i*;

$VOLATILITY_{i,j,t}$ = standard deviation of monthly stock returns over the 12 months prior to the forecast date;

$VOLUME_{i,j,t}$ = standardized trading volume over the 12 months prior to the forecast date;[13]

$INST\_HOLD_{i,j,t}$ = percentage of shares outstanding owned by institutional investors in the quarter before the forecast date;

$BM_{i,j,t}$ = ratio of book value of equity to market value at the end of the month before the forecast date;

---

[13] In light of the difference in the market microstructure between NASDAQ and NYSE/AMEX stocks (Atkins and Dyl 1997), we standardize the variable by sorting stocks into 100 portfolios separately for NASDAQ and NYSE/AMEX stocks, and then divide the rank by 100 to convert the value to the range between 0 and 1.

$EP_{i,j,t}$ = ratio of prior year's net income to market value at the end of the month before the forecast date;
$EXFIN_{i,t}$ = computed as in Bradshaw et al. (2006) and is the net amount of cash flow received from debt and equity financing activities as indicated in the Statement of Cash Flows for the current fiscal year, scaled by the market value of common equity;
$SIZE_{i,j,t}$ = logarithm of market value at the end of the month before the forecast date; and
$NSEG_{i,t}$ = logarithm of (1 + number of business segments of firm *j*).

Herrmann and Thomas (2005) examine whether analyst characteristics explain rounding. To investigate the relative importance of analyst characteristics in determining rounding, we estimate the following logistic model:

$$\begin{aligned} Prob(ROUND_{i,j,t} = 1) = F(&\beta_0 + \beta_{10}LAGACCU_{i,j,t} + \beta_{11}BROKERSIZE_{i,j,t} \\ &+ \beta_{12}FOR\_FREQ_{i,j,t} + \beta_{13}EXPERIENCE_{i,j,t} + \beta_{14}HORIZON_{i,j,t} \\ &+ \beta_{15}FIRMS\_FOL_{i,j,t} + \varepsilon_{i,j,t}). \end{aligned} \tag{2}$$

We construct the analyst characteristic variables in the same manner as Herrmann and Thomas (2005) where rounding analysts are compared to other analysts following the same firm:

LAGACCU = accuracy of the analyst's prior year's EPS forecast for the firm;
BROKERSIZE = based on the number of analysts employed by the brokerage house;
FOR_FREQ = number of forecasts the analyst made for the firm in a given year;
EXPERIENCE = number of years the analyst has followed the firm;
HORIZON = number of calendar days from the date of the forecast to the date of the earnings announcement; and
FIRMS_FOL = number of firms followed by the analyst.

The detailed definitions of these variables are provided in Appendix A. We also examine the number of industries followed (*IND_FOL*). Industry following is highly correlated with *FIRM_FOL* so we do not include both in our regressions. Results are similar when we substitute *IND_FOL* for *FIRM_FOL* in our analysis.

To investigate the incremental importance of firm-level variables versus analyst characteristics in determining rounding, we estimate Model (3) that combines Models (1) and (2) and examine Pseudo R^2 and significance levels of the variables:

$$\begin{aligned} Prob(ROUND_{i,j,t} = 1) = F(&\beta_0 + \beta_1 ALAGEPS_{i,t} + \beta_2 VOLATILIITY_{i,j,t} + \beta_3 VOLUME_{i,j,t} \\ &+ \beta_4 INST\_HOLD_{i,j,t} + \beta_5 BM_{i,j,t} + \beta_6 EP_{i,j,t} + \beta_7 EXFIN_{i,t} \\ &+ \beta_8 SIZE_{i,j,t} + \beta_9 NSEG_{j,t} + \beta_{10}LAGACCU_{i,j,t} \\ &+ \beta_{11}BROKERSIZE_{i,j,t} + \beta_{12}FOR\_FREQ_{i,j,t} \\ &+ \beta_{13}EXPERIENCE_{i,j,t} + \beta_{14}HORIZON_{i,j,t} \\ &+ \beta_{15}FIRMS\_FOL_{i,j,t} + \varepsilon_{i,j,t}). \end{aligned} \tag{3}$$

To mitigate the problem that cross-sectional dependence inflates test statistics, we estimate all regression models by year and report the mean coefficient. To mitigate any time-series dependence problems we further correct the Fama-MacBeth t-statistics for serial correlations of one lag.

Table 3 provides the means for each variable and a correlation matrix. Panel A reveals that the differences in means between rounded and non-rounded forecasts for firm-level variables are all significant in the predicted direction. Rounded forecasts have higher levels of lagged absolute value of EPS; the followed firms have less volatile stock returns, have lower stock volume, have lower institutional holdings, have high book-to-market and EP ratios (i.e., are "low-growth" stock), and

TABLE 3 (continued)

Detailed definitions of analyst-characteristic variables are provided in Appendix A.

Variable Definitions:
Firm-Characteristic Variables:
$ALAGEPS_{i,t}$ = absolute value of year t–1 actual EPS of firm i;
$VOLATILITY_{i,j,t}$ = standard deviation of monthly stock returns over the 12 months prior to the forecast date;
$VOLUME_{i,j,t}$ = standardized trading volume over the 12 months prior to the forecast date;
$INST\_HOLD_{i,j,t}$ = percentage of shares outstanding owned by institutional investors in the quarter before the forecast date;
$BM_{i,j,t}$ = ratio of book value of equity to market value at the end of the month before the forecast date;
$EP_{i,j,t}$ = ratio of prior year's net income to market value at the end of the month before the forecast date;
$EXFIN_{i,t}$ = net amount of cash flow received from external (debt and equity) financing activities for the current fiscal year as determined from the Statement of Cash Flows scaled by the market value of common equity;
$SIZE_{i,j,t}$ = logarithm of market value at the end of the month before the forecast date; and
$NSEG_{i,t}$ = logarithm of (1 + number of business segments of firm i).
Analyst-Characteristic Variables:
$LAGACCU$ = accuracy of the analyst's prior year's EPS forecast for the firm;
$BROKERSIZE$ = based on number of analysts employed by the brokerage house;
FOR_FREQ = number of forecasts the analyst made for the firm in a given year;
$EXPERIENCE$ = number of years the analyst has followed the firm;
$HORIZON$ = number of calendar days from the date of the forecast to the date of the earnings announcement;
$FIRMS\_FOL_i$ = number of firms followed by the analyst; and
IND_FOL_i = number of firms followed by the analyst.

receive less external financing from the capital market. Analysts also tend to round more in firms with more business segments and in larger firms.

The results of analyst-specific characteristics are reported in Table 3, Panel B and are less consistent with predictions. The differences in *LAGACCU*, *FOR_FREQ*, and *HORIZON* are statistically significant in the predicted direction. However, the differences in the other analyst characteristics (*BROKERSIZE*, *EXPERIENCE*, *FIRMS_FOL*, and *IND_FOL*) are statistically significant in the wrong direction. Similar to Herrmann and Thomas (2005), we find that rounding analysts have more *EXPERIENCE* than non-rounding analysts. As Herrmann and Thomas (2005) acknowledge in their paper, these results are inconsistent with analyst rounding when they lack information because experienced analysts should be more informed than less experienced analysts. One possible explanation for this result is that analysts become less concerned with forecast accuracy as their experience increases. The analyst career-concern literature suggests that analysts are rewarded for accuracy in their early years in order to build a reputation (e.g., Hong and Kubik 2003; Groysberg et al. 2008), but that they are compensated less for accuracy as their tenure with the firm increases. This suggests that the benefit of exerting forecasting effort is greater for analysts with less experience and could explain why rounding increases with analyst experience. The correlations presented in Panel C of Table 3 convey a message similar to the results provided in Panel A and B.

Table 4 provides the results of our multivariate logistic regressions. We first report the results for Model (1) that includes only the firm-level variables. Consistent with our predictions, we find that the coefficients on all firm characteristics have the predicted signs. The results indicate that analysts are more likely to round their forecasts for firms with a larger magnitude of the prior year's EPS. Consistent with brokerage and investment banking fees influencing analysts' incentives, we find that analysts are more likely to round their forecasts in firms with low trading volume, high book-to-market and earning-to-price ratios, and low external financing. Consistent with complexity increasing the likelihood of rounding, we find that large firms with more business segments have more rounded forecasts. The coefficients on volatility and institutional holdings also bear the correct signs but are insignificant.

Model (2) replicates Herrmann and Thomas's (2005) model. The results show that all coefficients on analyst characteristics have the correct signs but are statistically significant for only *FOR_FREQ* and *HORIZON*. The average Model (2) pseudo R^2 (2.35 percent) is about one-third of the average Model (1) pseudo R^2 (6.71 percent). This simple comparison suggests that firm-level variables collectively are more important in determining rounding than analyst characteristics. In Model (3) we include both sets of variables. The coefficients as well as the t-statistics on firm-characteristics are similar to those of Model (1). Including firm characteristics increases the statistical significance of the coefficients on analyst variables considerably. Now all analyst characteristics are significant except the size of the brokerage firm. The pseudo R^2 increases to 9.02 percent for Model (3), suggesting that both firm characteristics and analyst characteristics are important for explaining rounding behavior. Again, Model (3) indicates that more experienced (as opposed to less experienced) analysts are more likely to round their EPS forecasts.

In untabulated results we find that the results are robust to the exclusion of negative forecasts and are generally stronger for forecasts greater than $1 where rounding is more prevalent. We also find qualitatively similar results for subsample periods before and after the year 1996, with the results being stronger for the recent period.

Firm-Level Analysis

One potential issue with the logistic regression reported above is that it gives a greater weight to firms followed by more analysts. To determine whether this weighting impacts our conclusions

This table provides the regression results of the following logistic models:

$$\begin{aligned} \mathit{Prob}(\mathit{ROUND}_{i,j,t} = 1) = F(&\beta_0 + \beta_1 \mathit{FEPS}_{i,j,t} + \beta_2 \mathit{VOLATILITY}_{i,j,t} + \beta_3 \mathit{VOLUME}_{i,j,t} + \beta_4 \mathit{INST\_HOLD}_{i,j,t} \\ &+ \beta_5 \mathit{BM}_{i,j,t} + \beta_6 \mathit{EP}_{i,j,t} + \beta_7 \mathit{SIZE}_{i,j,t} + \beta_8 \mathit{FOLLOW}_{i,j,t} + \beta_9 \mathit{DISPERSION}_{i,j,t} \\ &+ \beta_{10} \mathit{LOGAGE}_{i,j,t} + \varepsilon_{i,j,t}). \end{aligned}$$

$$\begin{aligned} \mathit{Prob}(\mathit{ROUND}_{i,j,t} = 1) = F(&\beta_0 + \beta_1 \mathit{BROKERSIZE}_{i,j,t} + \beta_2 \mathit{FOR\_FREQ}_{i,j,t} + \beta_3 \mathit{EXPERIENCE}_{i,j,t} \\ &+ \beta_4 \mathit{HORIZON}_{i,j,t} + \beta_5 \mathit{FIRMS\_FOL}_{i,j,t} + \varepsilon_{i,j,t}). \end{aligned}$$

$$\begin{aligned} \mathit{Prob}(\mathit{ROUND}_{i,j,t} = 1) = F(&\beta_0 + \beta_1 \mathit{FEPS}_{i,j,t} + \beta_2 \mathit{VOLATILITY}_{i,j,t} + \beta_3 \mathit{VOLUME}_{i,j,t} + \beta_4 \mathit{INST\_HOLD}_{i,j,t} \\ &+ \beta_5 \mathit{BM}_{i,j,t} + \beta_6 \mathit{EP}_{i,j,t} + \beta_7 \mathit{SIZE}_{i,j,t} + \beta_8 \mathit{FOLLOW}_{i,j,t} + \beta_9 \mathit{DISPERSION}_{i,j,t} \\ &+ \beta_{10} \mathit{LOGAGE}_{i,j,t} + \beta_{11} \mathit{BROKERSIZE}_{i,j,t} + \beta_{12} \mathit{FOR\_FREQ}_{i,j,t} \\ &+ \beta_{13} \mathit{EXPERIENCE}_{i,j,t} + \beta_{14} \mathit{HORIZON}_{i,j,t} + \beta_{15} \mathit{FIRMS\_FOL}_{i,j,t} + \varepsilon_{i,j,t}). \end{aligned}$$

We estimate the regressions cross-sectionally each year and then calculate t-statistics using the Fama-MacBeth approach with Newey-West correction for autocorrelations for 1 year lag.

Variable definitions are provided in Table 3.

drawn from Model (1), we next conduct our analysis at the firm level. We estimate the following model:

$$\begin{aligned} \mathit{PCT\_ROUND}_{i,t} = &\beta_0 + \beta_1 \mathit{ALAGEPS}_{i,t} + \beta_2 \mathit{VOLATILITY}_{i,t} + \beta_3 \mathit{VOLUME}_{i,t} \\ &+ \beta_4 \mathit{INST\_HOLD}_{i,t} + \beta_5 \mathit{BM}_{i,t} + \beta_6 \mathit{EP}_{i,t} + \beta_7 \mathit{EXFIN}_{i,t} + \beta_8 \mathit{SIZE}_{i,t} \\ &+ \beta_9 \mathit{NSEG}_{i,t} + \varepsilon_{i,t}, \end{aligned} \tag{4}$$

TABLE 5

Firm-Level Regression of Percentage of Rounded Forecasts on Firm Characteristics

Model (4)	Predicted Sign	Estimate	t-statistic

BM	+	0.091***	4.55
EP	+	0.049	0.70
EXFIN	−	−0.042***	−3.55
SIZE	?	0.025***	6.24
NSEG	+	0.061***	8.55
Average n per year		1,823	
R^2		8.95	

, * Indicate significance at the 5 percent and 1 percent levels, respectively.
This table provides the regression results of the following model:

$$PCT\_ROUND_{i,t} = \beta_0 + \beta_1 ALAGEPS_{i,t} + \beta_2 VOLATILITY_{i,t} + \beta_3 VOLUME_{i,,t} + \beta_4 INST\_HOLD_{i,t} + \beta_5 BM_{i,t} + \beta_6 EP_{i,t} + \beta_7 EXFIN_{i,t} + \beta_8 SIZE_{i,t} + \beta_9 NSEG_{i,t} + \varepsilon_{i,t}.$$

We estimate the regressions using the Fama-MacBeth approach with Newey-West correction for autocorrelations for 1 year lag.
Variable definitions are provided in Table 3.

where $PCT\_ROUND_{i,t}$ is the percentage of analysts whose most recent forecasts for firm *i*'s year *t* EPS end with a 0 or 5 in the penny digit. All other variables are defined similarly to that of Model (1) and are calculated as of the month end before the earnings announcement.

Table 5 provides the regression results. The table presents slightly stronger results than those for the analyst-level analysis in Table 4. The coefficients on all independent variables have the predicted sign except *VOLATILITY*, for which the coefficient is insignificant. The results confirm that analysts tend to round their EPS forecasts more for firms with a larger magnitude of EPS, low trading volume, low institutional ownership, low external financing, high book-to-market, large size, and more business segments. These findings indicate that economic considerations such as brokerage commissions, underwriting fees, and business complexity have a significant impact on analysts' effort to improve forecast precision.

Analyst-Level Analysis: Earnings Response Coefficients for Rounded Forecasts

We next examine whether a rounded forecast can be used as a convenient proxy for the greater likelihood that the forecast is a noisier predictor of future earnings. We provide the following regression:

$$RET_{j,t} = \beta_0 + \beta_1 SURP_{i,j,t} + \beta_2 \mathbf{ROUND}_{i,j,t} + \beta_3 \mathbf{ROUND}_{i,j,t} \times \mathbf{SURP}_{i,j,t}, \qquad (5)$$

where, $RET_{j,t}$ is the size-adjusted stock returns for firm *j* over the three-day window around earnings announcement of year *t*. $SURP_{i,j,t}$ is the difference between actual EPS reported by the firm *j* and forecast EPS reported by analyst *i*, scaled by price for earnings announcement *t*. Our objective is to determine whether the coefficient β_3, on the interaction term between *ROUND* and *SURP*, is negative. This would indicate that the earnings response coefficient is biased down due to investors placing less weight on rounded forecasts in forming their expectations. Model (5) allows us to examine unconditionally whether rounded forecasts have a lower response coefficient than non-rounded forecasts.

Model (6) controls for other factors identified in the literature as influencing the magnitude of earnings response coefficients:

$$\begin{aligned} RET_{j,t} = {} & \beta_0 + \beta_1 SURP_{i,j,t} + \beta_2 \boldsymbol{ROUND}_{i,j,t} + \beta_3 \boldsymbol{ROUND}_{i,j,t} \times \boldsymbol{SURP}_{i,j,t} \\ & + \beta_4 VOLATILITY_{i,j,t} + \beta_5 SIZE_{i,j,t} + \beta_6 BM_{i,j,t} + \beta_7 DISPERSION_{i,j,t} \\ & + \beta_8 VOLATILITY_{i,j,t} \times SURP_{i,j,t} + \beta_9 SIZE_{i,j,t} \times SURP_{i,j,t} + \beta_{10} BM_{i,j,t} \times SURP_{i,j,t} \\ & + \beta_{11} DISPERSION_{i,j,t} \times SURP_{i,j,t} + \beta_{12} |SURP_{i,j,t}| \times SURP_{i,j,t} + e_{i,j,t}. \end{aligned} \tag{6}$$

More volatile firms (*VOLATILITY*) are likely to have noisier earnings estimates; larger firms (*SIZE*) have lower earnings response coefficients; and book-to-market (*BM*) is a measure of growth. We include *DISPERSION* because prior research (e.g., Burgstahler and Chuk 2010; Kim 2010) find that analyst forecast dispersion affects earnings response coefficients and include |*SURP*| to control for the nonlinearity in ERC as documented in Freeman and Tse (1992) and Kinney et al. (2002). We calculate *DISPERSION* as the standard deviation of individual forecasts scaled by the absolute value of the mean of the forecasts. For completeness we interact all control variables with *SURP*.

Table 6 provides the results of the two regressions. The results for Model (5) indicate that the earnings response coefficient (ERC) is 0.1687 for non-rounded forecasts and 0.1275 (0.1687 – 0.0412) for rounded forecasts. The ERC on rounded forecasts is approximately 24 percent lower than that on non-rounded forecasts (–0.0412/0.1687) and the difference is statistically significant. The final two columns of the table present the results for Model (6). Consistent with prior research, the results show that the earnings response coefficient is lower for large firms, firms with more dispersed forecasts, and for larger earnings surprises. More importantly, the coefficient β_3 remains negative and statistically significant. These results suggests that a rounded forecast is a more noisy proxy of the investors' expectations since investors respond less to forecast errors made by rounding analysts.

Note that in Table 1 we find that rounded forecasts are more optimistically biased than other forecasts. This indicates that, on average, actual earnings are lower than forecast earnings for rounding analysts. Since this optimistic bias is predictable *ex ante*, investors should be aware of this bias and not respond to the predictably negative earnings surprise based on rounded forecasts. Thus, assuming market efficiency, the coefficient on *ROUND* should be 0. However, the results in Table 6 indicate that the coefficient on *ROUND* is negative and significant ($\beta_2 = -0.0011$ or -0.0014).[14] This is consistent with investors not fully adjusting their expectations for the optimistic bias in rounded forecasts and being surprised by the negative earnings surprise. Thus, overall our results suggest that investors place less weight on forecasts made by rounding analysts than those made by other analysts, but that they do not fully adjust their expectations for the predictable optimism in rounded forecasts.

---

[14] In untabulated results we find that the mean earnings announcement return is 0.14 percent for rounded forecasts and 0.30 percent for others. This suggests that the earnings announcement return is about 0.16 percent lower for rounded forecasts than other forecasts, which translates to annualized return difference of about 13.33 percent. However, given the short holding period and high portfolio turnover, this *ex ante* predictable return difference could be difficult to exploit after taking into consideration trading costs.

TABLE 6

An Examination of Investor Response to Unexpected Earnings (Actual EPS Less Forecast EPS Scaled by Price) at Earnings Announcements and the Impact of Rounding

	Model (5)		Model (6)

*, **, *** Indicate significance at the 10 percent, 5 percent, and 1 percent levels, respectively.

This table reports the regression results of the following model:

$$\begin{aligned} RET_{j,t} = {} & \beta_0 + \beta_1 SURP_{i,j,t} + \beta_2 ROUND_{i,j,t} + \beta_3 ROUND_{i,j,t} \times SURP_{i,j,t} + \beta_4 VOLATILITY_{i,j,t} + \beta_5 SIZE_{i,j,t} \\ & + \beta_6 BM_{i,j,t} + \beta_7 DISPERSION_{i,j,t} + \beta_8 VOLATILITY_{i,j,t} \times SURP_{i,j,t} + \beta_9 SIZE_{i,j,t} \times SURP_{i,j,t} \\ & + \beta_{10} BM_{i,j,t} \times SURP_{i,j,t} + \beta_{11} DISPERSION_{i,j,t} \times SURP_{i,j,t} + \beta_{12} |SURP_{i,j,t}| \times SURP_{i,j,t} + e_{i,j,t}. \end{aligned}$$

We estimate the regressions using the Fama-MacBeth approach with Newey-West correction for autocorrelations for 1 year lag.

Variable Definitions:
$RET_{j,t}$ = size-adjusted stock returns over the three days surrounding earnings announcement for stock *j* for year *t*;
$SURP_{i,j,t}$ = actual earnings less the most recent forecast made by analyst *i* for firm *j* scaled by price; and
$ROUND_{i,j,t}$ = an indicator variable that takes the value of 1 if a forecast ends with a 0 or 5, and 0 otherwise.
Control Variables Included in the Regression:
$VOLATILITY_{i,j,t}$ = standard deviation of monthly returns over the 12 months prior to forecast date;
$SIZE_{i,j,t}$ = logarithm of market cap;
$BM_{i,j,t}$ = ratio of book value of equity to market cap;
DISPERSION = forecast dispersion as of the month before a forecast was issued;
$|SURP_{i,j,t}|$ = absolute value of $SURP_{i,j,t}$.

VI. CONCLUSION

We examine analysts' tendency to round forecasts to the nearest 0 or 5 cents. We conjecture that analysts *choose* the level of effort that they put into forecasting and that this choice influences their decision to round. The less effort analysts exert in forecasting earnings, the more uncertain they are about the penny digit of the forecast and the more likely they are to round.

We suggest that an intuitive reason that an analyst may choose not to exert effort in forecasting with "to the penny" precision exists in cases where firms have larger EPS numbers. As the level of EPS increases: (1) the economic importance of the penny digit declines and so is less relevant to investors; and (2) the precision of the analyst's information is not as likely to hold to the penny. We show that rounding is an increasing function of the level of EPS. Actual EPS displays no such rounding with the proportion of 0s and 5s remaining at 20 percent.

Our next tests examine whether compensation incentives influence analysts' incentives to round. We suggest that analysts are likely to exert less effort in forecasting earnings for firms that are of less interest to investors and so generate less brokerage business. We also suggest that analysts will exert less effort in firms that are unlikely to be raising new financing since these firms are unlikely to become investment-banking clients. Our results are consistent with these predictions. We show that rounding occurs more frequently in low-growth firms, in firms with low trading volume and low institutional holdings, and in firms that are not accessing capital markets for new financing. We also examine whether rounding is more likely to occur when the firm being followed has a more complex business. This could occur because, relative to a less complex firm, the analyst has to exert more effort to understand the business. Our results suggest that rounding is more likely in larger firms and in firms with more business segments.

We investigate the stock price response to rounded forecasts to determine whether researchers could use "rounding" as a simple proxy for lower information content of the forecast. Our results indicate that investors respond less to "unexpected earnings" (actual minus forecast earnings) when the forecast is rounded. This is consistent with a rounded forecast being a noisier proxy of the market's expectation of earnings. We also find that, on average, rounded forecasts have a small but significantly lower announcement return than other forecasts. This suggests that the optimistic bias in rounded forecasts may not be always fully anticipated by investors.

Our paper offers several avenues for future research. Do management disclosures affect the extent of rounding since this could reduce the cost to the analyst of providing a more accurate forecast? As analysts' incentives change, do we observe changes in rounding behavior? How have changes in the information environment (e.g., the ability of analysts to observe other analysts' forecasts) affected incentives to round? Are there ways to better separate true 0s and 5s from rounded 0s and 5s so that we could better predict when and where analysts are exerting more or less effort? This, in turn, could help researchers and investors better forecast future earnings and lead to better predictions on how investors will respond to earnings.

APPENDIX A

DEFINITIONS OF ANALYST CHARACTERISTIC VARIABLES

$LAGACCU_{i,j,t}$ = accuracy of analyst *i*'s most recent forecast of firm *j*'s earnings in year *t*–1. It is calculated as the maximum absolute forecast error for analysts following firm *j* in year *t*–1 minus the absolute forecast error of analyst *i* following firm *j* in year *t*–1, scaled by the range of absolute forecast errors for analysts following firm *j* in year *t*–1;

$BROKERSIZE_{i,j,t}$ = broker size, calculated as the number of analysts employed by the broker employing analyst *i* following firm *j* in year *t* minus the minimum number of analysts employed by brokers for analysts following firm *j* in year *t*, scaled by the range of broker size for analysts following firm *j* in year *t*;

FOR_FREQ$_{i,j,t}$ = forecast frequency, calculated as the number of firm *j* forecasts made by analyst *i* in year *t* minus the minimum number of firm *j* forecasts for analysts following firm *j* in year *t*, scaled by the range of the number of firm *j* forecasts issued by analysts following firm *j* in year *t*;

EXPERIENCE$_{i,j,t}$ = analyst's firm experience, calculated as the number of years of firm-specific experience for analyst *i* following firm *j* in year *t* minus the minimum number of years of firm-specific experience for analysts following firm *j* in year *t*, scaled by the range of years of firm-specific experience of analysts following firm *j* in year *t*;

HORIZON$_{i,j,t}$ = forecast horizon, calculated as the number of calendar days from forecast date to the earnings announcement date for analyst *i* following firm *j* in year *t* minus the minimum forecast horizon for analysts following firm *j* in year *t*, scaled by the range of forecast horizon for analysts following firm *j* in year *t*;

FIRM_FOL = number of firms followed, calculated as the number of firms followed by analyst *i* following firm *j* in year *t* minus the minimum number of firms followed by analysts following firm *j* in year *t*, scaled by the range of the numbers of firms followed by analysts following firm *j* in year *t*; and

IND_FOL$_{i,j,t}$ = number of industries followed, calculated as the number of industries followed by analyst *i* following firm *j* in year *t* minus the minimum number of industries followed by analysts following firm *j* in year *t*, scaled by the range of the numbers of industries followed by analysts following firm *j* in year *t*.

The Timeliness of Bad Earnings News and Litigation Risk

ABSTRACT: This study investigates whether the timely revelation of bad earnings news is associated with a lower incidence of litigation. The timeliness of earnings news is captured by a new measure based on the evolution of the consensus analyst earnings forecast. Holding total bad earnings news and other determinants of litigation constant, we find that earlier revelation of bad earnings news lowers the likelihood of litigation. This result holds for both settled and dismissed lawsuits. Further, we reconcile our findings with prior work that measures timeliness using managerial warnings via press releases. These tests suggest our findings are attributable to the ability of our timeliness measure to capture bad earning news revealed through disclosure channels beyond press releases.

the perception that management "hid the truth" and reduces damages by shortening the class period. This litigation reduction hypothesis predicts that timelier revelation of bad earnings news should reduce the likelihood of being sued and/or the costs of resolving lawsuits that do occur.

Prior work investigates the litigation reduction hypothesis using measures of the timeliness of bad earnings news based on management earnings "warnings" or "pre-announcements" via a press release. Early studies, such as Francis et al. (1994) and Skinner (1997), find that quarters triggering litigation are actually more likely to contain earnings warnings. Skinner (1997) suggests this result may be driven by endogeneity, as firms with worse earnings news have higher incentives to warn because of higher litigation risk. Skinner (1997) finds that earlier disclosure is associated with lower settlements after controlling for estimated shareholder damages. Field et al. (2005) explicitly control for endogeneity and find no relation between earnings warnings and the incidence of litigation in general, but document a negative relation between earnings warnings and the incidence of litigation after dismissed suits are excluded from their analysis.

We construct a new measure of the timeliness of *total* bad earnings news, which captures how quickly earnings news is revealed to the market using the evolution of analysts' consensus earnings forecasts. This new measure allows for a stronger test of the litigation reduction hypothesis for two reasons. First, our measure captures *all* bad earnings news revealed to the market, including instances where there are multiple news events. Earnings warnings delivered in companies' press releases are only one way in which earnings news can be revealed to the market. Alternative methods include analyst conference calls, presentations, webcasts, private communications (at least before Regulation FD), and analyst research. Liability under U.S. securities laws does not depend on any particular form or source for revelations that correct an inflated stock price. Thus, the litigation reduction hypothesis holds as long as total bad earnings news is revealed on a timelier basis, regardless of the method of revelation. Second, our measure is constructed using machine-readable data sources, allowing for larger sample tests and eliminating the need for costly and time-consuming hand collection of disclosure data (e.g., press release warnings).

Analysts' consensus forecasts are arguably the best available proxy for the market earnings expectation. We measure earnings news timeliness for the quarter triggering lawsuits by computing the proportion of total earnings news revealed up to each day in the quarter and then taking the average of the daily proportions. For example, assume the ultimate earnings revelation in a quarter is \$0.10 per share, the beginning forecast is \$0.50 per share, and the forecast on a given day is \$0.30. The proportion of the total news revealed up to that day is 50 percent (i.e., (0.50 – 0.30)/(0.50 – 0.10)). We calculate this proportion for each day and then compute the average across all days in the quarter. Thus, our timeliness measure captures the average daily proportion of total earnings news revealed to the market during the quarter triggering litigation.

Our sued sample consists of 423 securities class action lawsuits from 1996–2005. Consistent with prior research (e.g., Field et al. 2005; Johnson et al. 2007), we use a matched sample research design. Our first matched sample contains non-sued firms matched with sued firms based on total earnings news and disclosure window length. This ensures that sued and non-sued firms have similar total earnings news over the same time period, which helps control for the endogeneity noted by Skinner (1997). Specifically, for each sued firm-quarter (i.e., the quarter triggering the lawsuit), we select a non-sued firm from the same quarter with the closest total earnings news (i.e., the ultimate earnings revelation less the beginning-of-quarter consensus forecast, scaled by beginning-of-quarter stock price). Our second matched sample utilizes the predicted probability of litigation. Specifically, we estimate a litigation prediction model that expresses the probability of being sued as a function of economic determinants. Then, for each sued firm-quarter, we select the non-sued firm from the same quarter with bad earnings news and the closest predicted litigation probability.

Using each of the two matched samples, we find that timelier revelation of bad earnings news is associated with a lower threat of litigation. This negative relation applies to both settled and dismissed suits. In addition, our results are robust to controlling for numerous determinants of litigation risk, such as firm size, stock returns over the litigation quarter, the largest negative one-day return during the litigation quarter, and insider selling. Furthermore, our results are similar if we use alternative matching methods, such as matching on market capitalization and stock returns over the litigation quarter or matching on industry and the largest negative one-day stock return over the litigation quarter. These alternative matching methods provide evidence that our results are not driven by sued firms having larger stock price drops over the litigation quarter or over a short window. In addition, our results are not driven by innate differences between sued and non-sued firms. We find similar patterns when we benchmark sued firms against themselves by examining the speed of news revelation in non-litigation quarters.

We also reconcile our findings with those of prior studies by repeating our test with a timeliness measure based on managerial earnings warnings. We hand-collect data on management earnings warnings via press releases from Factiva and Lexis-Nexis for a random subsample of firms with large negative total earnings news. Following Field et al. (2005), we measure disclosure timeliness using an indicator variable for the presence of an earnings warning prior to the earnings announcement. Consistent with prior studies (e.g., Francis et al. 1994; Field et al. 2005), we find that sued firms are more likely to issue earnings warnings than non-sued firms. However, we find that bad earnings news is revealed earlier for non-sued firms than for sued firms when our new measure of the timeliness of total earnings news is used. This result suggests that the difference between our findings and those of prior studies is attributable to the ability of our timeliness measure to capture news revelation beyond management press releases.

This study makes three primary contributions. First, we provide additional evidence on Skinner's (1994) litigation reduction hypothesis. Our findings complement and extend those of Field et al. (2005) by providing new evidence that timelier revelation of bad earnings news deters not only suits that are eventually settled, but also those that are dismissed by the court. The finding regarding dismissed suits is particularly important because these are cases where the courts find that the factual allegations do not convincingly lead to an inference of fraud. Exposure to such litigation is arguably the very type of litigation that, from a policy perspective, we may want timely revelation of bad earnings news to preempt. Second, our results demonstrate the importance of considering multiple revelation channels when studying managerial disclosure. Our findings suggest that examining only press releases yields an incomplete picture of managerial disclosure and can lead to erroneous inferences.

Third, we construct a new measure of timeliness that captures how quickly total bad earnings news is revealed to the market. This measure is available on a firm-year or firm-quarter basis, based on machine-readable data, and explicitly focused on earnings news. This measure can be used in future research to investigate the impact of timely earnings news revelations. For example, this measure could be used to examine whether the market reacts differently to the timely revelation of earnings news (holding the magnitude of news constant), or whether the timeliness of earnings news affects firm/managerial reputation, the cost of capital, or information asymmetries between managers and outsiders. In addition, the measure could be used to test changes in the information environment due to regulations, such as Regulation FD, that might impact disclosure practices.

Section II discusses the institutional background and related literature. Section III describes the research design and reports results. Section IV concludes.

II. INSTITUTIONAL BACKGROUND AND RELATED LITERATURE

Securities litigation involving bad earnings news generally alleges violations of Rule 10b-5. The elements of a Rule 10b-5 violation are "(1) a misstatement or omission of (2) a material fact (3) made with intent (4) that the plaintiff justifiably relied on (5) causing injury in connection with the purchase or sale of securities" (Skinner 1994). Suits involving bad earnings news, therefore, allege either an *omission* (i.e., the failure to disclose earnings news on a timely basis) and/or a *misstatement* (i.e., an incorrect earlier forecast or statement of fact), either of which may satisfy element (1). A significant negative stock price reaction to the news demonstrates both materiality (element (2)) and causation (element (5)). Element (4) is generally presumed under the fraud on the market theory (see Francis et al. 1994).

In order to survive a motion to dismiss under the Private Securities Litigation Reform Act of 1995 (PSLRA), the plaintiffs' complaint must allege facts that lead to a strong inference of fraudulent intent. Thus, earnings disclosure cases often turn on whether the alleged omission or misstatement was *intentional*. Under the high pleading standard of the PSLRA, a mere stock price drop accompanying the release of bad news is insufficient to withstand a motion to dismiss. Rather, the circumstances surrounding the alleged omission or misstatement are critical and the appearance that managers are trying to hide information is beneficial to plaintiffs. Likely because they must allege facts that give a strong inference of intent, plaintiffs generally present as many facts as possible to demonstrate that it is implausible that managers were ignorant of the bad news prior to its revelation and commonly allege both omissions and misstatements.

The first study to formally propose that the timelier revelation of bad earnings news could reduce the expected costs of litigation is Skinner (1994). Skinner (1994) and several later studies (e.g., Skinner 1997; Field et al. 2005; Healy and Palepu 2001) outline three factors that support the litigation reduction hypothesis. First, timely disclosure weakens the claim that managers (1) withheld bad earnings news they should have disclosed and/or (2) made false statements in light of this undisclosed news to keep the share price inflated. Although plaintiffs can rarely prove when management first learned of bad earnings news, the late revelation of bad news helps create the *ex post appearance* that managers had "something to hide." The late revelation of bad news enhances the credibility of plaintiffs' claims that managers kept the share price inflated until the fraud could no longer be maintained, which is a common claim in disclosure lawsuits. Second, timely disclosure shortens the nondisclosure period, reducing the size of the plaintiff class and potential damages in a lawsuit. Third, timely disclosure may mitigate large negative stock price reactions, which are a trigger for litigation. Disclosing part of the bad news earlier spreads the bad news out over time and helps avoid a large, one-time price drop. In addition, timely disclosure may enhance managers' perceived competence or credibility, engendering a less severe negative stock price reaction.[1]

Several studies (Francis et al. 1994; Skinner 1997; Field et al. 2005) examine the litigation reduction hypothesis using managerial earnings warnings or preannouncements via press releases to measure the timeliness of management disclosure of bad earnings news.[2] These studies use the presence of an earnings warning prior to the earnings announcement (Field et al. 2005), whether the earnings warning is issued before or after the quarter-end (Francis et al. 1994; Skinner 1997), or the number of days between the press release date and a benchmark point (i.e., quarter-end, quarter-beginning, or earnings announcements) (Francis et al. 1994; Skinner 1997) as their measures of the timeliness of bad earnings news.[3] The key common factor in these studies is that all of the measures are contingent on an explicit earnings warning.

---

[1] In addition to Rule 10b-5, firms may also be liable under Section 11 of the Securities Act of 1933 in cases where they are issuing securities. While Section 11 has a lower intent standard, the second and third reasons for the litigation hypothesis still hold in a Section 11 context. As such, we include these cases in our primary analysis, but find in supplementary analysis that results are virtually identical when these cases are excluded.

[2] A related line of research examines how the risk of shareholder litigation affects managers' disclosure choices (e.g., Skinner 1994; Kasznik and Lev 1995; Baginski et al. 2002; Rogers and Van Buskirk 2009).

[3] One exception is Francis et al. (1994), who also examine earnings disclosures through analyst reports, and find that managers sometimes disclose news to analysts who then disseminate the information in the pre-Regulation FD environment. Francis et al. (1994) also examine analyst forecasts for a small sample of firms to test whether analysts anticipate negative earnings news to a larger extent for non-sued firms than for sued firms. They find no such evidence. However, they do not examine the timing of the forecast revisions during the litigation quarter.

Francis et al. (1994) find that sued firms issue voluntary earnings disclosures prior to the earnings announcement at a significantly higher rate than non-sued firms. This result appears inconsistent with the litigation reduction hypothesis. Skinner (1997) confirms the main finding of Francis et al. (1994) with a different design. He compares press release disclosure patterns of sued firms during quarters that triggered litigation to their disclosure practices in non-litigation quarters and finds that earnings warnings via press releases are much more common in litigation quarters than in non-litigation quarters. However, Skinner (1997) notes that endogeneity could drive the positive relation between disclosure timeliness and litigation risk. In other words, firms with worse bad earnings news have stronger incentives to issue earnings warnings *because* they face higher litigation risk. After controlling for estimated shareholder damages, Skinner (1997) finds some evidence that timelier disclosure is associated with lower settlement amounts, consistent with the litigation reduction hypothesis. Using a simultaneous equation approach to address the endogeneity problem noted by Skinner (1997), Field et al. (2005) find no significant relation between earnings warnings and litigation risk when examining all suits. After excluding dismissed suits, Field et al. (2005) find that earnings warnings are negatively related to the incidence of litigation, consistent with the litigation reduction hypothesis.

Overall, Skinner's (1997) findings with respect to settlements and the Field et al. (2005) findings with respect to the incidence of settled suits provide some support for the litigation reduction hypothesis. However, there is no evidence to date that early disclosure of bad earnings news helps to prevent non-meritorious litigation (i.e., litigation that would be dismissed if filed), which is an important type of litigation to deter.

In this study, we offer several reasons why it is important to consider total earnings news when testing the litigation reduction hypothesis. First, press releases are only one channel through which managers can reveal bad earnings news to the market. Managers can also reveal negative earnings news through public disclosure channels such as conference calls (Tasker 1998; Frankel et al. 1999), presentations at conferences (Bushee et al. 2009), and company websites (Deller et al. 1999). Further, anecdotal evidence and academic research indicate that, at least prior to Regulation FD, managers often engaged in private communication with institutional investors and financial analysts through closed conference calls, one-on-one meetings, or phone conversations.[4] Analysts also conduct research through industry analysis and the polling of customers and suppliers, which can lead to the revelation of earnings news. Finally, whistle-blowing by a former employee or a press article may reveal news to the market.

Second, the bad news revelation is not the source of legal liability under U.S. securities laws. Rather, the prior failure to disclose when a duty to disclose exists (an omission) or a prior misstatement (e.g., a misleading or knowingly false earnings projection) exposes firms to litigation.[5] The revelation leading to litigation does not need to come from management or take any particular form (e.g., an explicit warning). Rather, a wide array of disclosure sources and forms may reveal the alleged fraud and result in litigation. For example, Dyck et al. (2010) detail numerous cases in which external whistleblowers revealed the fraud.

---

[4] Managers continue to conduct one-on-one meetings with analysts and institutional investors post-Regulation FD. For example, in a survey by Rivel Research (NIRI 2001), 79 percent of the 577 National Investor Relations Institute member companies claim that they hold one-on-one meetings to the same or greater extent post-Regulation FD.

[5] There is no overarching duty to disclose all material information immediately (e.g., *In re Parametric Technology Corp. Securities Litigation*, 300 F. Supp. 206 (D. Mass. 2001); Rogers and Van Buskirk 2009). However, if a firm decides to disclose information, it must disclose the whole truth such that the disclosure is not misleading (Rogers and Van Buskirk 2009). In addition, if a firm makes an initial disclosure, many courts have extended the "whole truth" doctrine to provide a "duty to update" if the information is still relevant to market participants (e.g., Langevoort and Gulati 2004). Finally, a duty to disclose arises when corporate insiders trade based on material, non-public information (e.g., *San Leandro Emergency Med. Plan v. Philip Morris*, 75 F. 3d 801 (2d Cir. 1996)).

Finally, the importance of taking total earnings news into account is also supported by the materiality requirement of Rule 10b-5, which considers the total "information mix" available to the market (see *Basic, Inc. v. Levinson*, 485 U.S. 224 1988; Francis et al. 1994). Whether any managerial statement or failure to disclose is misleading is determined in the context of the total information available to the market, including information from non-management sources. Non-timely bad news revelation of any form, such as a warning, a conference call, or a press article simply leads to the *appearance* that management had "something to hide," which may make plaintiffs' allegations of *intentional* omissions or prior misstatements by management seem more credible. Thus, the timeliness of total bad earnings news available to the market is likely of the highest importance with respect to the litigation reduction hypothesis.

Unfortunately, it is difficult to gather data regarding many of these revelation channels, and some are simply unobservable. For example, conference call and conference presentation transcripts became available only recently, and managers' private communication with financial analysts is largely unobservable. Fortunately, analysts' earnings forecasts are a widely used proxy for market expectations and provide a measure of all earnings news that reaches market participants (e.g., Bartov et al. 2002). Analysts' forecasts incorporate information developed through independent analyst research, as well as information released in all disclosures, including those otherwise unavailable to researchers, such as private communication with managers. Thus, this proxy is a broad measure that captures the timeliness of total earnings news during the litigation quarter and complements prior research that examines official press releases.

In our empirical analysis below, we examine two related issues. First, we examine whether the timelier revelation of total bad earnings news is linked to lower litigation risk. Second, we examine the source of the information that drives analyst forecast revisions, which generate our measure of the timeliness of total earnings news.

III. SAMPLE, RESEARCH DESIGN, AND EMPIRICAL RESULTS

Sued Sample

We use the Securities Class Action Services (SCAS) database from RiskMetrics to identify all class action securities lawsuits filed in Federal court from 1996–2005. We end our sample in 2005 because our later tests require data on settlement decisions, which generally take several years to resolve. Table 1 summarizes our sample selection process. We require lawsuits to allege losses in connection with common equity and defendant firms must have data available for our tests on CRSP and Compustat. Similar to Field et al. (2005), we exclude cases that involve restatements of prior financial statements (i.e., accounting irregularities) because it is less likely that timely disclosure of, say, fictitious revenue will deter litigation.

Since we measure earnings news and its timeliness using analyst forecasts, we require firms to have data available in I/B/E/S. We further require firms to have unfavorable (i.e., negative) earnings news in the fiscal quarter that triggered the lawsuit.[6] We define earnings news as the "earnings

---

[6] We collected a random sample of 20 lawsuits for which there was no indication of bad news using the evolution of the analyst consensus forecast from I/B/E/S. Ninety percent of these cases involved issues other than the disclosure of bad earnings news, such as IPO "laddering" cases or results of FDA drug trials. The remaining two cases did appear to involve some disclosure of bad earnings news before the earnings announcement, but these firms had limited analyst coverage, so changes in the consensus analyst forecast per I/B/E/S did not reflect this news. Importantly, however, these disclosures occurred late in the quarter (87 percent of the quarter elapsed on average since the last announcement date), so our screen does not appear to exclude timely revelation lawsuits and does not bias our sample in favor of lawsuits with late revelation of news.

TABLE 1
Sample Selection

All lawsuits filed from 1996 to 2005	2,456
Less: Firms without data from CRSP and Compustat	(813)
	1,643
Less: Suits involving a restatement	(335)
	1,308
Less: Firms without necessary data from I/B/E/S	(463)
	845
Less: Suits without bad earnings news in litigation quarter	(422)
Final Sued Sample (firm-quarters)	423

revelation" at the end of the class period (the period over which fraud is alleged) minus the first consensus forecast of the quarter, scaled by stock price at the beginning of the quarter. We measure the first consensus forecast of the quarter at least one day after the announcement of prior quarter earnings. We do this to ensure forecasts have been updated for the prior quarter's earnings announcement, but results are similar if we measure the first consensus forecast at least two weeks after the prior quarter announcement date. For cases where the end of the class period coincides with the official earnings announcement date (about 17 percent of cases), we define the "earnings revelation" as actual earnings in I/B/E/S. For all other cases, the "earnings revelation" is defined as the consensus forecast at the end of the class period.[7]

We refer to the time from the beginning consensus forecast to the end of the class period as the "quarterly revelation window." For cases where the class period ends on the earnings announcement date, the median length of the quarterly revelation window is 91 days. For all other cases, the median length of this window is 61 days. Overall, our final sued sample contains 423 sued firm-quarters that had unfavorable earnings news in the litigation quarter. Since few firms in our sample (15 out of 408 unique firms) have more than one suit, we often refer to firm-quarters as "firms" throughout the remainder of the study for brevity.

Matched Samples

Following prior work on litigation risk (e.g., Field et al. 2005; Johnson et al. 2007), we employ a matched-pairs design using sued firms and similar non-sued firms. A matched-pairs design yields two benefits in our setting versus the alternative of using the universe of firms. First, in some of our tests to follow, we hand-collect data regarding earnings warnings and information from analyst research reports. Resource and time constraints prevent us from collecting these data for the universe of firms. Drawing upon a matched sample of similar sued and non-sued firms therefore facilitates our data-collection efforts.

---

[7] When the class period does not end at the earnings announcement date, we measure the consensus up to five days after the end of the class period to allow for a lag in the incorporation of bad news into analysts' forecasts. The results hold separately for both the suits whose class periods end before the earnings announcement dates and those whose class periods end at the earnings announcement dates.

Second, using a matched design yields a comparable set of non-sued control firms that plausibly could have been sued, but were not. Obtaining a set of non-sued firms similar to our sued firms is critical because *ex ante* litigation risk may endogenously affect firms' decisions to release news on a timely basis. For example, firms with low *ex ante* litigation risk may have little incentive to release bad news in a timely fashion (Skinner 1997). Simply adding controls for litigation risk in a regression using the universe of firms is problematic because litigation risk is nonlinear and is concentrated in a fairly small subsample of firms (Nelson and Pritchard 2008). A matched pairs design allows us to overcome this issue by explicitly matching sued firms with similar non-sued firms. We use two matched control samples of non-sued firms, one matched on total earnings news and one matched on total litigation risk.

Earnings News-Matched Sample

Since our focus is on the timeliness of bad earnings news, our first control sample is matched on total bad earnings news. Prior studies that test the litigation reduction hypothesis often select matching control observations using bad earnings news (e.g., Francis et al. 1994; Field et al. 2005). Therefore, for each sued firm, we select a non-sued firm from the same quarter with the closest total bad earnings news. For lawsuits where the class period ends on the earnings announcement day, total earnings news for matched firms is measured as actual earnings minus the beginning consensus forecast, scaled by beginning stock price. For all other cases, total earnings news for the matched firm is measured as the "ending" consensus forecast less the beginning consensus forecast, scaled by beginning stock price. The ending consensus forecast for non-sued firms is measured by the same number of days after the prior quarter earnings announcement date as the ending consensus forecast for the corresponding sued firm. This procedure helps ensure that the length of quarterly revelation window is equal for sued and non-sued firms. Our final earnings news-matched control sample contains 423 matching non-sued firms with unfavorable earnings news of a similar magnitude to sued firms.

Probability-Matched Sample

Because factors other than bad earnings news also affect litigation risk, we use a second control sample of non-sued firms matched on overall litigation probability. Specifically, we estimate the following logistic regression:

$$\begin{aligned} PROB(SUED = 1) = F(\alpha &+ \beta_1 NEWS + \beta_2 SIZE + \beta_3 RET + \beta_4 BM + \beta_5 HIGHLIT \\ &+ \beta_6 VOLATILITY + \beta_7 SHARE\_TURN + \beta_8 FOLLOW + \beta_9 MIN\_RET \\ &+ \beta_{10} SKEWNESS + \beta_{11} INSIDER). \end{aligned} \tag{1}$$

SUED is an indicator variable equal to 1 for observations in our sued sample, and 0 for all non-sued firm-quarters with bad earnings news (the last consensus less than the first consensus) in the Compustat-CRSP-I/B/E/S universe. The covariates in Equation (1) are variables that affect litigation risk (see, e.g., Francis et al. 1994; Jones and Weingram 1996; Johnson et al. 2000; Palmrose and Scholz 2004; Field et al. 2005; Johnson et al. 2007; Nelson and Pritchard 2008). Detailed variable definitions are provided in Appendix A. In general, firms with higher market capitalization (*SIZE*), higher analyst following (*FOLLOW*), greater share turnover (*SHARE_TURN*), lower book-to-market (*BM*), and firms in high litigation risk industries (*HIGHLIT*) are more likely to be sued. In addition, firm-quarters with poor earnings news (*NEWS*), negative stock returns (*RET*), high return volatility (*VOLATILITY*), larger one-day negative returns (*MIN_RET*), more negative skewness (*SKEWNESS*), and higher abnormal insider selling

(*INSIDER*) are associated with higher litigation risk.[8] We find that all coefficients from Equation (1), except *HIGHLIT*, are significant at conventional levels in the predicted direction (untabulated).

For each sued firm, we select the non-sued firm from the same quarter that has negative earnings news and the closest predicted probability from Equation (1). Our final probability-matched control sample contains 423 matching non-sued firms with characteristics from Equation (1) similar to our sued sample.

Research Design

To test the litigation reduction hypothesis, we compare earnings news timeliness in our sample of sued firms to earnings news timeliness in our control samples on a univariate and multivariate basis. Our timeliness measure is defined as the average proportion of total news revealed up to a given day during the quarterly revelation window. To illustrate, assume that a hypothetical quarterly revelation window is only four days, the beginning consensus forecast is \$0.50 per share, and the ultimate earnings revelation is \$0.10 per share, implying total (unscaled) news of \$0.40 per share during the quarterly revelation window.

If the consensus forecast was revised to \$0.30 on the second day of the quarterly window, then 50 percent [(\$0.50 – \$0.30)/(\$0.50 – \$0.10)] of the total news had been revealed at that point. If the consensus forecast is revised to \$0.20 on day three of the quarterly window, then 75% [(\$0.50 – \$0.20)/(\$0.50 – \$0.10)] of the total news was revealed up to that day. Finally, if the consensus forecast is revised to \$0.10 on the final day of the revelation period, then 100 percent of the news was revealed at that point. Averaging these figures for each day yields our timeliness measure, which is 56 percent [(0% + 50% + 75% + 100%)/4] in this example. Hence, our measure captures the timeliness of the revelation of total news. We refer to this as *TIMELINESS* for each firm. Higher (lower) values of this variable imply more (less) timely revelation of bad earnings news.[9,10]

A potential, broader measure of total news is stock returns. Several prior studies utilize measures of timeliness based on stock returns over a given time period (e.g., Butler et al. 2007; Beekes and Brown 2006, 2007). However, utilizing returns has drawbacks that accompany the potential benefits. Most importantly, returns capture information beyond short-term earnings news. Utilizing a measure based on stock returns therefore makes it more difficult to determine the implications of our findings for managerial disclosure policy. This is particularly important given that prior accounting studies focus on litigation risk and bad *earnings* news disclosures. We therefore use earnings news revealed through analyst forecast revisions to provide evidence with respect to managerial disclosure choices. In untabulated tests, we find similar, but slightly weaker, results when we use stock returns to measure news timeliness.

Although we select matched control samples to try to neutralize key differences between sued and non-sued firms, we control for any remaining differences in a multivariate framework (Cram et al. 2009). Specifically, we estimate the following conditional logistic regression (variables are defined in Appendix A):

---

[8] In addition to its relation to litigation, Billings (2008) finds insider trading is related to the timing of disclosures.

[9] We recognize that the analysts' consensus forecast may not always go down in a monotonic fashion. We find that 7 percent of sued firms and 14 percent of non-sued earnings-matched firms experience an "over-correction" at some point during the revelation window (i.e., analysts revise their forecast upward). However, the results are similar if we exclude these observations from the analyses.

[10] Our measure assumes that analysts revise their forecasts when new information is revealed to the market. This assumption is reasonable in instances where the firm has an active analyst following. However, we recognize that some firms have a fairly small, inactive analyst following (and in our setting, given their size, would be unlikely to face securities litigation). For these firms, our measure is less appropriate as it is unlikely to capture the timeliness of information revealed to the market.

$$PROB(SUED = 1) = F(\beta_1 TIMELINESS + \beta_2 NEWS + \beta_3 SIZE + \beta_4 RET + \beta_5 BM + B_6 HIGHLIT + \beta_7 VOLATILITY + \beta_8 SHARE\_TURN + \beta_9 FOLLOW + \beta_{10} MIN\_RET + \beta_{11} SKEWNESS + \beta_{12} INSIDER). \qquad (2)$$

We use conditional logistic regression because it is more appropriate for the matched-sample analysis that matches observations based on both outcome (i.e., the dependent variable) and selected control variables (see, e.g., Hosmer and Lemeshow 2000; Johnson et al. 2007; Cram et al. 2009; Armstrong et al. 2010). However, the results are similar if we use standard logistic regression (untabulated). In Equation (2), *SUED* is an indicator variable equal to 1 if an observation is in our sued sample. *SUED* is equal to 0 for observations in our matched samples. The litigation reduction hypothesis predicts that the coefficient on *TIMELINESS*, β_1, will be negative.

Main Results

Univariate Results

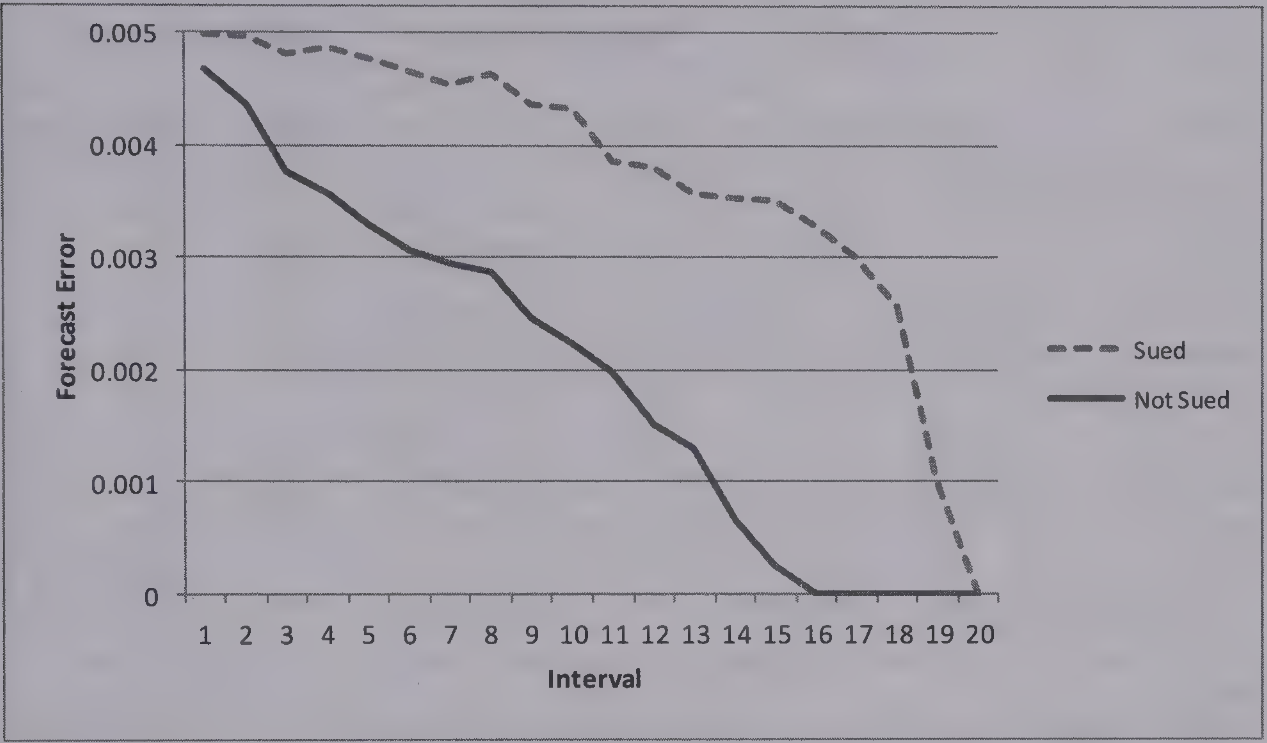
We begin with a graphical depiction of our main finding. For each sued and non-sued firm in our earnings news-matched sample, we divide the quarterly revelation window for each firm into 20 equal intervals. We then calculate the difference between the consensus forecast and the ultimate earnings revelation, scaled by stock price, at each interval. Figure 1 displays the evolution of the consensus for sued firms and non-sued firms matched on earnings news. By construction, total earnings news (as measured by the decline in the consensus) is nearly identical for sued and non-sued firms. However, Figure 1 reveals a stark difference in the news timing. Bad earnings news is revealed much earlier for firms that are not sued. For example, at the halfway point of the revelation window, over 55 percent of the bad news is revealed on average for non-sued firms, compared to less than 25 percent for sued firms (untabulated).

Table 2 contains descriptive statistics for our sued and non-sued samples. Consistent with the litigation reduction hypothesis, mean and median values of *TIMELINESS* are significantly higher for non-sued firms relative to sued firms. For the median earnings news- (probability)-matched control firm, a daily average of roughly 45 percent (35 percent) of total earnings news has been revealed throughout the quarter. For the median sued firm, the daily average of revealed news is about 12 percent. These differences are significant ($p < 0.01$).

As expected, there is no significant difference in total earnings news between sued firms and non-sued firm matched on earnings news. There is also no significant difference in earnings news between sued firms and non-sued firms matched on litigation probability. The mean level of bad earnings news for sued (non-sued) firms involves an earnings revelation that is 1.35 percent (1.13 percent to 1.17 percent) of market equity lower than the beginning consensus forecast. Other characteristics, such as size, returns, analyst following, etc. are significantly different between sued firms and control firms matched on earnings news. These differences, however, are generally not significant for control firms matched on litigation probability.

Although the probability-matched control sample is more effective in neutralizing differences in litigation determinants, we present findings using both control samples for the following reason. Some of our later tests involve hand-collection for sued and non-sued firms from managerial press releases and analyst research reports, and we want to ensure that the total magnitude of forecast revisions, and the window over which they are measured, is held constant across samples. Also, we want to ensure that the control sample used in these tests is fairly similar to those used in prior studies like Field et al. (2005). The control sample matched on earnings news is best suited for this purpose. Furthermore, as described in the subsection below entitled "Alternate Matched Control Samples," inferences regarding the effect of *TIMELINESS* on litigation risk are statistically and economically similar regardless of the control sample used.

FIGURE 1
Timeliness of Forecast Revisions in the Quarter Leading up to the Class Period End Date for Firms Sued and Firms Not Sued



We obtain all bad news class action securities lawsuits not involving a restatement filed in Federal court from 1996–2005 from the RiskMetrics Securities Class Action Services (SCAS) database. For each sued firm, we select a match firm from the same quarter with the closest total earnings news. Total earnings news is the bad earnings revelation at the end of the class period less first consensus forecast of the quarter, scaled by stock price at the beginning of the quarter. For each firm in our sample, we measure the difference between the consensus forecast each day and the ultimate earnings revelation, scaled by beginning stock price. This difference, or forecast error, measures the extent to which the consensus forecast at any given time reflects the total earnings news of the quarterly period. For each firm we then divide the quarterly revelation window into 20 equal intervals, and calculate the median forecast error across firms by interval.

Table 3 presents correlations among the variables in Equation (2). Panel A presents correlations for the earnings news-matched sample. *TIMELINESS* is strongly negatively correlated with *SUED* (corr. = –0.30, $p < 0.01$). Panel B presents correlation for the probability-matched sample. *TIMELINESS* is again strongly negatively correlated with *SUED* (corr. = –0.36, $p < 0.01$). Other correlations are consistent with the patterns in Table 2.

Multivariate Results

Table 4 reports the results of estimating Equation (2) using conditional logistic regression. Panel A reports the results using the control sample matched on earnings news. To facilitate interpretation, we utilize the quintile rank of the *TIMELINESS* variable to estimate Equation (2) instead of the raw *TIMELINESS* measure (results are similar if we use the raw measure). There is a negative relation between *TIMELINESS* and the probability of a lawsuit ($p < 0.01$), even after controlling for stock returns and other variables from Equation (2). To assess the economic

*, **, *** Indicate t-tests and median tests of differences across groups significant at $p < 0.10$, 0.05, and 0.01, respectively.

We obtain all class action securities lawsuits not involving a restatement filed in Federal court from 1996–2005 from the RiskMetrics Securities Class Action Services (SCAS) database. For each sued firm, we select two sets of match firms. The match firm in the earnings news-match sample is selected from the same quarter with the closest total earnings news. The match firm in the litigation probability-match sample is selected based on a probability match procedure where the match is the non-sued firm with the closest predicted probability of litigation (using determinants from prior literature) in the quarter triggering litigation for sued firms.

PROB_LIT is the predicted probability of litigation using the litigation probability-match sample. Descriptive statistics are tabulated for the sample of sued firms and the two respective control samples.

Variables are defined in Appendix A.

significance of our findings, we include marginal effects for each parameter estimate, which are akin to slope coefficients in an OLS regression. Marginal effects vary across observations, depending on the predicted probability of being sued. To gauge the "average" marginal effect, we first compute the marginal effect for each observation in the sample and then calculate the sample mean of individual marginal effects. Results are similar if we compute the sample median of individual marginal effects.

Table 4 indicates that a one unit increase in ranked *TIMELINESS* (i.e., moving up from one quintile to the next in our *TIMELINESS* measure) is associated with a decrease in the probability of a lawsuit of 2.7 percentage points. In interpreting the marginal effect, it is important to note that the unconditional probability of a lawsuit in our sample is 50 percent, rather than the substantially lower rate present in the full population, due to our matched-pair design.

Parameter estimates for the control variables are generally significant in the predicted direction. Exceptions include stock price volatility and return skewness, which are insignificant at conventional levels. The pseudo R^2 is 39.5 percent, indicating that the covariates help explain the incidence of lawsuits reasonably well.

Table 4, Panel A also provides the results from estimating Equation (2) separately for dismissed and settled lawsuits based on the final disposition of the case, each with their respective

TABLE 4 (continued)

---

*, **, *** Denote significance at the 0.10, 0.05, and 0.01 levels, respectively (two-tailed).
This table reports the results of a conditional logit regression examining the impact of timely news revelation on the incidence of litigation. We obtain all class action securities lawsuits not involving a restatement filed in Federal court from 1996–2005 from the RiskMetrics Securities Class Action Services (SCAS) database. In Panel A, for each sued firm, we select a match firm from the same quarter with the closest total earnings news. In Panel B, for each sued firm, the match is the non-sued firm with the closest predicted probability of litigation (using determinants from prior literature) in the quarter triggering litigation for sued firms. Column (1) contains the regression results for all firms, Column (2) contains the regression results for dismissed suits, and Column (3) contains the results for settled suits. Marginal effects are calculated as the mean of the individual marginal effects evaluated at each sample observation (Greene 2003).
All variables are defined in Appendix A.

matching non-sued firms.[11] This analysis addresses two issues. First, Field et al. (2005) find significant results only for settled suits and we want to assess the sensitivity of our findings to this distinction. Second, as discussed earlier, such non-meritorious litigation in dismissed suits is arguably the very type of litigation that capital market participants may want timely revelation of earnings news to preempt. The final columns of Panel A indicate that *TIMELINESS* is negatively related to litigation incidence for both dismissed and settled lawsuits. Thus, our main findings are not sensitive to the case outcome.[12]

Panel B of Table 4 reports the results of estimating Equation (2) using non-sued firms matched on litigation probability. Consistent with the results in Panel A, there is a significant negative relation between *TIMELINESS* and litigation risk. In fact, the results in Panel B are statistically and economically more significant than those in Panel A. For example, for all lawsuits, a one unit increase in ranked *TIMELINESS* is associated with a decrease in the probability of a lawsuit of 5.6 percentage points. In Panel B, we also find evidence that the deterrent effect of timely news revelation appears stronger for dismissed lawsuits (in terms of coefficient size and marginal effect). However, the negative relation between *TIMELINESS* and litigation risk holds for both dismissed and settled cases.[13,14]

---

[11] We also examine an alternative definition of non-meritorious cases, where we move cases that settle for small amounts (less than 0.5 percent of equity value) to the dismissed category. We find that *TIMELINESS* is still significant in each subsample.

[12] We perform two additional subsample tests. First, we assess the sensitivity of our findings to the magnitude of total earnings news as large drops in earnings news likely yield the strongest inference of fraud. Our results strengthen when we focus on cases with a larger magnitude of bad earnings news. Second, we examine the periods before and after the implementation of Regulation FD separately due to changes in the analyst environment at that time (see Gintschel and Markov 2004). The coefficient on *TIMELINESS* in the post-Regulation FD period drops about one-half from its value in the pre-Regulation FD period, although it is still economically and statistically significant. This evidence that the difference in news timeliness between sued and non-sued firms shrinks in the post-Regulation FD period is consistent with non-sued firms engaging in more private communication with analysts in the pre-Regulation FD period. However, because other major economic and regulatory events occurred in the 2000s (e.g., Sarbanes-Oxley), we are leery of drawing any definitive causal inferences from this finding.

[13] The significant coefficients on the control variables in Panel B of Table 4 (i.e., using the probability-matched sample) are sensitive to the use of conditional logistic regression. The coefficients on those controls are insignificant when we use normal logistic regression.

[14] We also examine a measure of bad news "smoothness," the extent to which the consensus forecast drops in a smooth, linear fashion over the quarter. We do this to ensure that *TIMELINESS* is capturing the effect of interest rather than some other construct. When included in Equation (2) along with *TIMELINESS*, this variable is insignificant. Thus, the timeliness of bad earnings news, not its "smoothness," appears to influence litigation risk. The *SMOOTHNESS* variable is described in detail in Appendix A.

There are at least two potential reasons that the *TIMELINESS* measure produces different results from those of Field et al. (2005), who find evidence of a negative relation between litigation risk and press release warnings only among settled suits. First, unlike Field et al. (2005), we do not use an instrumental variable (IV) approach. Larcker and Rusticus (2010) note that IV estimations can lead to a lack of statistical power. Thus, *TIMELINESS* may simply have more power to detect the negative relation between timely news revelation and litigation risk. Second, *TIMELINESS* captures earnings news revelation from sources beyond managerial press releases. Thus, *TIMELINESS* provides more granular information compared to an indicator variable based on the presence of an earnings warning. We provide more detail with respect to reconciling our results to those of Field et al. (2005) below, under "Reconciliation to Prior Work."

Overall, the results from Figure 1 and Tables 2 through 4 indicate consistently that timelier revelation of bad earnings news is associated with a lower incidence of litigation. This evidence supports the litigation reduction hypothesis.

Additional Analyses

Alternate Matched Control Samples

In addition to the two control samples used in Table 4, we also estimated Equation (2) using two alternative matched control samples. The first involves matching sued firms and non-sued firms on market capitalization and stock returns over the litigation quarter. The second involves matching on industry and negative one-day stock returns over the litigation quarter, similar to the procedure in Johnson et al. (2007). We do not tabulate results using these alternate samples, but statistical and economic significance is similar to that in Table 4.

Economic Significance in the Broad Population

Although a matched pair design helps isolate non-sued firms with earnings news and other litigation determinants similar to sued firms, such a procedure involves non-random sampling. Since securities litigation is a fairly rare event in the broad population of firms, our matched design over-samples sued firms and under-samples non-sued firms. The average probability of litigation in our samples is 50 percent, while the unconditional probability of being sued in the broad population is much lower. As a consequence, concerns arise as to whether our findings misstate the economic significance of *TIMELINESS* in affecting overall litigation rates.

To address this concern, we estimate Equation (2) using a logistic regression among all firms in the Compustat-CRSP-I/B/E/S universe with bad earnings news, i.e., those for which the last consensus is lower than the first consensus. Overall, we have 423 sued observations and 64,532 non-sued observations, for an unconditional litigation risk of roughly 0.65 percent. In untabulated results, we find that the coefficient on quintile-ranked *TIMELINESS* is -0.57 ($t = 8.41$, $p < 0.01$), with a mean (median) marginal effect of roughly 0.31 percent (0.05 percent) moving from one quintile to the next quintile, which is approximately 47 percent (8 percent) of the unconditional probability of being sued for bad earnings news in the overall population.[15] Thus, the effect of

---

[15] Since litigation risk is concentrated in a relatively small sample of firms in the broad population, the predicted probability of being sued in the full population of firms is highly right-skewed. As a result, the distribution of individual marginal effects in the full population is also highly right-skewed, which produces a mean marginal effect that is much higher than the median. The median marginal effect in the full sample (approximately 8 percent of the 0.65 percent base rate) is comparable to the mean and median marginal effects in the earnings-matched (approximately 5 percent of the 50 percent base rate) and probability-matched samples (approximately 11 percent of the 50 percent base rate).

TIMELINESS on this baseline risk appears economically significant when compared to the probability of litigation in the overall population.

Fundamental Differences between Sued and Non-Sued Firms

One potential concern with our main findings is that sued firms' information environments may be fundamentally different from those of non-sued firms. Perhaps news tends to be less timely, or analysts react in a less timely manner to news, for sued firms versus non-sued firms due to differences in industry membership, business models, or other factors. Thus, our main analysis may simply be picking up innate differences in information flow or other firm characteristics between sued and non-sued firms.

We address this concern in two ways. First, we benchmark sued firms against themselves and estimate Equation (2) utilizing sued firms that also had negative earnings news in the quarter prior to the quarter that triggered litigation. We measure total earnings news in this quarter as the ending consensus forecast less the beginning consensus, scaled by beginning stock price. The results from this regression are in Table 5. Again, we find that negative earnings news is less timely in the litigation quarter, even when sued firms are compared to themselves.

Second, we assess whether differences in timeliness between sued and non-sued firms exist outside the litigation quarter by examining the first fiscal quarter that begins after the filing of the lawsuit. We require total news in this quarter to be negative for sued firms and match these firms to non-sued firms in the same quarter with the closest total news. Figure 2 plots the timeliness of earnings news using the same methods as in Figure 1. The striking difference in timeliness between sued and non-sued firms evident in Figure 1 disappears. In fact, news revelation appears slightly more timely for sued firms, but a t-test reveals no significant difference in *TIMELINESS* across samples ($t = -0.29$, untabulated).[16] Combined with the above result (utilizing sued firms as their own control), this evidence suggests that our main finding is not driven by industry or firm differences between sued and non-sued firms.

Timeliness Measurement

The final potential concern pertains to how we measure our *TIMELINESS* variable, and whether this definition of timeliness could somehow "mechanically" lead to our results. This argument proceeds as follows. The *TIMELINESS* measurement period for sued firms ends at the class period end date, when sued firms often reveal bad news and suffer a very large one-day stock price drop. Alternatively, non-sued firms do not necessarily have a bad news event at the end of their measurement period. Thus, the lower likelihood of a significant news event for non-sued firms at the end of the measurement window could lead to the lower *TIMELINESS* measure for sued firms as compared to non-sued firms.

While it is difficult to separate this argument regarding a mechanical relation from the effect of interest in our study, we conduct an additional untabulated test. First, for each sued firm we calculate the distance between the end of the class period and the largest one-day stock price drop during the quarter. This distance measure is less than or equal to 14 days for 75 percent of sued firms. Using our probability-matched sample, we then take the date of non-sued firms' largest one-day stock price drop and add the distance variable for the matching sued firm in order to create a "pseudo-class period" over which to measure the timeliness of earnings news for non-sued firms. Using this alternative measure of timeliness, we find results that are statistically and economically

---

[16] Inferences are similar if we examine the patterns in Figure 2 using a multivariate framework as in Table 4. In addition, we also compare sued and matched non-sued firms in the fiscal quarter prior to the lawsuit quarter and find patterns virtually identical to those presented in Figure 2 (no significant difference in news timeliness).

n	356		

*, **, *** Denote significance at the 0.10, 0.05, and 0.01 levels, respectively (two-tailed).

This table reports the results of a logistic regression examining the impact of the timely revelation of bad news on the incidence of litigation. We obtain all class action securities lawsuits not involving a restatement filed in Federal court from 1996–2005 from the RiskMetrics Securities Class Action Services (SCAS) database. Consistent with Skinner (1997), we benchmark sued firms against themselves, and estimate Equation (2) utilizing those sued firms that also had negative earnings news in the quarter prior to the quarter that triggered litigation.

All variables are defined in Appendix A.

similar to those observed in our main analyses. Thus, our results do not appear to be mechanically driven by how we construct our measure.[17]

Reconciliation to Prior Work

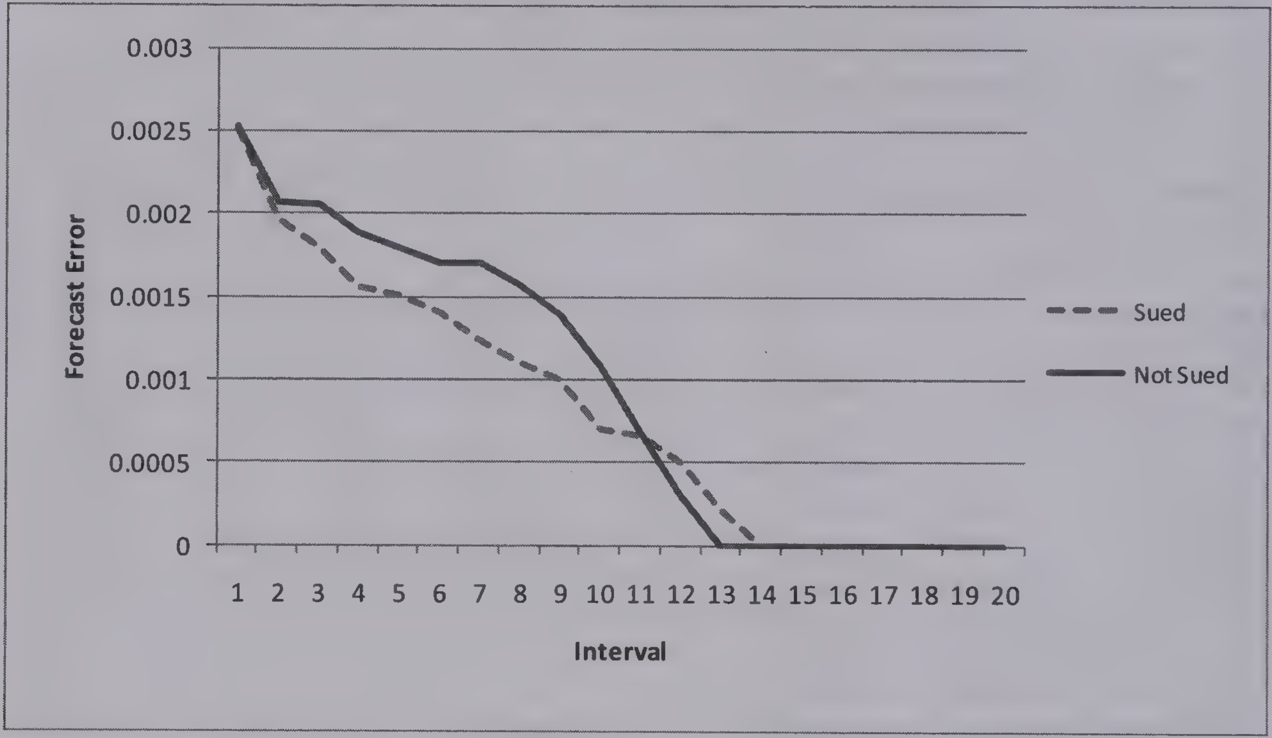
Our main finding indicates that non-litigation quarters involve timelier revelation of bad news. However, a number of prior studies consistently find that quarters triggering litigation contain more managerial earnings warnings in the form of press releases than non-litigation quarters (Francis et al. 1994; Skinner 1997; Field et al. 2005). How can these two results be reconciled? One explanation is that our timeliness measure captures sources of news revelation beyond earnings warnings. Another possibility is that the different results may be attributable to different samples, time periods, or design choices.

To ensure the negative relation we document between *TIMELINESS* and litigation risk is attributable to our measure, we conduct the following test. We randomly select 100 sued firms with total news earnings equal to at least 0.20 percent of share price and their earnings news-matched

---

[17] As an additional test, we also find similar results if we measure *TIMELINESS* using the proportion of total earnings news that is revealed up to the midpoint of the quarterly revelation window. This measure is not influenced by the revelation of news at the very end of the measurement period.

FIGURE 2
Timeliness of Forecast Revisions after the Class Period for Firms Sued and Firms Not Sued



This figure is constructed in an identical fashion to Figure 1, except that we focus on the first quarter after the filing of the lawsuit. For each firm we then divide the quarterly revelation window into 20 equal intervals, and calculate the median forecast error across firms by interval.

firm, to maintain comparability to Field et al. (2005). The results are similar if we limit the sample to dismissed suits, settled suits, or suits with earnings news of at least 1 percent of market value of equity. For these 200 firm-quarters, we search Factiva and Lexis-Nexis for earnings warnings in the form of a press release during the litigation quarter. For press releases that give explicit earnings guidance or warn of lower earnings or sales before the earnings announcement date, we code an indicator variable, *WARNING*, equal to 1. We then estimate the following logistic regressions, the first of which is similar to the specification used in prior studies:

$$PROB(SUED = 1) = F(\alpha + \beta_1 WARNING + \beta_2 NEWS + \beta_3 SIZE + \beta_4 RET + \beta_5 HIGHLIT + \beta_6 VOLATILITY + \beta_7 SHARE\_TURN); \quad (3a)$$

$$PROB(SUED = 1) = F(\alpha + \beta_1 TIMELINESS + \beta_2 NEWS + \beta_3 SIZE + \beta_4 RET + \beta_5 HIGHLIT + \beta_6 VOLATILITY + \beta_7 SHARE\_TURN). \quad (3b)$$

The only difference between Equations (3a) and (3b) is that Equation (3a) uses *WARNING* to proxy for timely disclosure (consistent with prior work), while Equation (3b) uses our timeliness measure.[18] Estimates are presented in Table 6. In the first column, for Equation (3a), the coefficient

---

[18] Equation (3a) includes the significant variables from Field et al. (2005, Table 4, column 1). Since we wish to reconcile to prior studies, we estimate an unconditional model, but results are similar if a conditional model is used.

TABLE 6

Timeliness versus Earnings Warnings

	(1) Earnings Warning		(2) Timeliness	
Variable	**Coeff.**	**t-statistic**	**Coeff.**	**t-statistic**
Intercept	8.56	(−5.34)***	−6.13	(−3.78)***
WARNING	1.78	(3.77)***		
TIMELINESS			−0.97	(−4.84)***
NEWS	−0.18	(−1.51)	−0.16	(−1.35)
SIZE	0.62	(3.90)***	0.64	(3.56)***
RET	−0.06	(−5.51)***	−0.05	(−4.64)***
HIGHLIT	0.71	(1.40)	0.58	(1.03)
VOLATILITY	0.19	(1.16)	0.27	(1.54)
SHARE_TURN	0.48	(1.50)	0.44	(1.44)
Pseudo R^2	50.8%		54.2%	
n	200		200	

*, **, *** Denote significance at the 0.10, 0.05, and 0.01 levels, respectively (two-tailed).

This table reconciles our results to those obtained by the prior literature. More specifically, we select 100 sued and their corresponding earnings news match firms and collect whether an earnings warning was issued. We then run our main analysis with the earnings warning indicator variable in Column (1) and our timeliness measure in Column (2).

All variables are defined in Appendix A.

on *WARNING* is *positive* and significant ($t = 3.77$, $p < 0.01$), which is consistent with the findings of prior work in this area (e.g., Field et al. 2005).[19] In the second column, for Equation (3b), the coefficient on *TIMELINESS* is *negative* and significant ($t = -4.84$, $p < 0.01$).

Thus, like prior studies, we find that sued firms are more likely to warn than non-sued firms. However, the overall timeliness of news revelation for sued firms is lower compared to non-sued firms. This evidence suggests that our measure of timeliness, which focuses on revisions to the consensus analyst forecast, captures forms of news revelation that are not captured by managerial earnings warnings. In the next section, we explore the sources of news that drives revisions to the consensus analyst forecast in our sample.

What Drives Revisions to the Consensus Analyst Forecast?

We examine analysts' research reports to provide evidence on the source behind revisions to the consensus analyst forecast. We begin by using the same 100 sued and 100 non-sued firms used in Table 6, and collect all meaningful research reports from the beginning of the quarter to the end of the class period available in Investext.[20] We find meaningful reports for 115 total firms (68 sued and 47 non-sued), including 18 matched pairs. Untabulated analysis of these reports yields two main results. First, the overwhelming majority of analyst revisions (89 percent) are driven by managerial disclosures, including both earnings warnings and other, nontraditional managerial disclosures, such as conference calls, presentations, webcasts, and private communications. Second, while non-sued firms' revisions are less likely to be triggered by explicit earnings warnings compared to sued firms (44 percent versus 94 percent, $p < 0.01$), non-sued firms' revisions are more likely to be triggered by nontraditional management disclosures (33 percent versus 6 percent, $p < 0.05$).[21] Overall, this analysis helps validate our new measure as a way to capture all forms of managerial disclosure.

---

[19] We attempted to further reconcile our results to Field et al. (2005) by collecting data on management disclosure of earnings news from the same quarter in the prior year. Our findings with respect to the primary variables are very similar to Field et al. (2005). We (they) find that 84 percent (84 percent) of sued firms warn in the litigation quarter compared to 34 percent (44 percent) of non-sued firms. For the prior period disclosure instrumental variable, we (they) find that 16 percent (19 percent) of sued firms provide disclosure, while 18 percent (22 percent) of non-sued firms provide disclosure. While we do not find that the instrument is positively linked to warnings, we do find that this variable is negative and insignificant when we run the second-stage regression (inserting the predicted probability of a warning from the first stage), as in Field et al. (2005). We also find similar results using subsamples (e.g., dismissed versus settled, restricting to 1 percent of *MVE* for earnings news).

IV. CONCLUSION

This study explores whether the timelier revelation of bad earnings news is linked to lower litigation risk. To examine this question, we utilize a new measure that captures the timeliness of total earnings news via the evolution of the consensus analyst forecast. This timeliness measure captures all earnings news revealed to the market including traditional management disclosure, nontraditional management disclosures (e.g., conference calls, presentations, and private communication) and non-management earnings news. Thus, the measure captures the timeliness of earnings news across all revelation channels. Utilizing this measure, we find that timely revelation of bad earnings news deters litigation. This result holds for both settled and dismissed lawsuits, suggesting that timely news revelation deters the incidence of all types of litigation.

This study has two limitations. First, our measure of earnings news timeliness requires active analyst coverage, so it will not be effective for many small firms. Second, we can never be sure that managers who revealed news in an apparently untimely fashion actually had possession of this news at an earlier date. In fact, plaintiffs can rarely be sure of the date of managerial knowledge acquisition. All empirical studies of disclosure therefore suffer from this limitation. Nevertheless, the implications of our findings for managers clearly indicate that it is best to release bad earnings news early to reduce the chance of litigation.

[20] We ignore research reports that represent mere reactions to the prior quarter's earnings announcements and focus only on reports that discuss a "material" revision to the analyst's prior earnings forecast for the current quarter. We define a material revision as one that is at least equal to 0.1 percent of share price. If reports by multiple analysts all pertain to the same news revelation (e.g., a management earnings warning), then we retain a single report.

[21] The proportions cited above are for the 18 matched-pairs (36 firms) only. However, non-sued to sued comparisons among all 115 firms are inferentially similar (53 percent versus 91 percent for warnings, $p < 0.01$, and 30 percent versus 4 percent for non-traditional disclosures, $p < 0.01$).

APPENDIX A
VARIABLE DEFINITIONS

BM = ratio of total shareholder equity (from Compustat) in the litigation quarter to market value of equity at the beginning of the quarterly revelation window;

FOLLOW = number of analysts following the firm during the quarterly revelation window;

HIGHLIT = indicator variable that is set to 1 when the firm operates in a high litigation risk industry as defined by Francis et al. (1994) (SIC codes 2833–2838 and 8731–8734 (biotech); SIC codes 3570–3577 and 7370–7374 (computer); 3600–3674 (electronics); and 5200–5961 (retail)), and is equal to 0 otherwise;

INSIDER = for sued firms, net selling (shares sold minus bought/shares outstanding) of insiders over the class period, less net selling over the previous 365 days. For non-sued firms, net selling (shares sold minus bought/shares outstanding) of insiders over the 365 days ending in the current quarter, less net selling over the previous 365 days;

MIN_RET = minimum daily return over the litigation quarter;

NEWS = for sued firms, this is the "earnings revelation" at the end of the class period less the beginning consensus forecast (which is measured at least one day after the prior quarter earnings announcement) scaled by stock price one day after the prior quarter earnings announcement. When the class period end date corresponds with an earnings announcement date, the "earnings revelation" is equal to I/B/E/S actual EPS. When the class period end date does not correspond with an earnings announcement, the "earnings revelation" is defined as the consensus forecast as of the class period end date plus up to five days;

NEWS = for non-sued firms is defined as follows. For lawsuits where the class period ends on the earnings announcement day, total earnings news for matched non-sued firms is measured as actual earnings minus the beginning consensus, scaled by beginning stock price. For all other cases, total earnings news is measured as the "ending" consensus less the beginning consensus, scaled by beginning stock price. The "ending" consensus for earnings-matched non-sued firms is measured as the same number of days after the prior quarter earnings announcement date as the ending consensus for the corresponding sued firm. For probability-matched non-sued firms, the ending consensus is the last consensus forecast of the quarter. The consensus forecast at any given date is the median of the most recent forecast available for all analysts. This variable is expressed as a percentage;

RET = cumulated daily stock return beginning the day after the prior quarter earnings announcement and ending on the class period end date. Expressed as a percentage;

SHARE_TURN = average daily turnover (volume/shares outstanding) over the quarterly revelation window, expressed as a percentage;

SIZE = log of market value (in billions) of the firm obtained from CRSP and measured on the day after the prior quarter's earnings were announced;

SKEWNESS = skewness of daily stock returns over the litigation quarter;

SMOOTHNESS = average absolute daily deviation of the consensus revision from the smoothest revision that could have occurred had the firm released its earnings news evenly throughout the litigation quarter. The smoothest possible revision is defined as the total earnings news divided by the number of days in the quarterly announcement window;

TIMELINESS = average proportion of total news that was revealed up to a given day in the quarterly revelation window. The quarterly revelation window is the first day after the prior quarter earnings announcement to the end of the class period. To illustrate, assume that a quarterly revelation window is four days, the beginning consensus forecast is \$0.50 per share, and the ultimate earnings revelation is \$0.10 per share, implying total (unscaled) news of \$0.40 per share during the quarterly revelation window. If the consensus forecast was revised to \$0.30 on the second day of the quarterly window, then 50 percent [(\$0.50 – \$0.30)/(\$0.50 – \$0.10)] of the total news had been revealed at that point. Furthermore, assume that the consensus forecast is revised to \$0.20 on day three of the quarterly window, then 75 percent [(\$0.50 – \$0.20)/(\$0.50 – \$0.10)] of the total news was revealed up to that point. Finally, the consensus forecast is revised to \$0.10 on the fourth day, suggesting 100 percent of the news was disclosed. Hence, the value of our timeliness measure for this example is 56 percent (0% + 50% + 75% + 100%)/4. Hence, higher (lower) values of this variable imply more (less) timely revelation of bad earnings news;

VOLATILITY = standard deviation of daily returns over the quarterly revelation window, expressed as a percentage; and

WARNING = indicator variable that is set equal to 1 when a firm issues an earnings warnings or preannouncement of earnings, and is equal to 0 otherwise.

Mandatory IFRS Adoption and Institutional Investment Decisions

Annita Florou
King's College London

Peter F. Pope
City University London

ABSTRACT: We examine whether the mandatory introduction of International Financial Reporting Standards leads to an increase in institutional investor demand for equities. Using a large ownership database covering all types of institutional investors from around the world, we find that institutional holdings increase for mandatory IFRS adopters. Changes in holdings are concentrated around first-time annual reporting events. Second, we document that the positive IFRS effects on institutional holdings are concentrated among investors whose orientation and styles suggest they are most likely to benefit from higher quality financial statements, including active, value, and growth investors. These results are consistent with holdings changes being associated with the financial reporting regime change. Finally, we show that increased institutional holdings are concentrated in countries in which enforcement and reporting incentives are strongest, and where the differences between local GAAP and IFRS are relatively high. Overall, our study helps shed new light on the channels by which IFRS information becomes impounded in market outcomes.

I. INTRODUCTION

Regulators have claimed that investors and issuers of securities will benefit from the mandatory adoption of International Financial Reporting Standards (IFRS). They claim that for many countries IFRS require higher quality measurement and recognition rules; they are more transparent than local GAAP; and that common IFRS financial reporting across countries will enhance comparability (EC Regulation No. 1606/2002, European Council 2002). Theory predicts that the mandated introduction of higher quality financial reporting can improve stock market liquidity and reduce the cost of capital (Leuz and Wysocki 2008), and empirical evidence on the market outcomes of mandatory IFRS adoption generally supports these predictions (Daske et al. 2008; Li 2010). An indirect implication of such findings is that market participants find IFRS reporting to be incrementally informative. In this paper we test directly whether mandated IFRS adoption affects institutional investor decisions. Institutional investors are an interesting group of financial statement users because they are economically important and because they are often regarded as sophisticated users who have the time, resources, and expertise to process the information in complex financial statements. Establishing a causal link between mandatory IFRS reporting and institutional investor decision outcomes helps to shed new light on the channels by which IFRS information becomes impounded in market outcomes.

Using a global sample of 10,852 unique firms from 45 countries over the 2003–2006 period, we report a number of results that are new to the literature. First, after controlling for standard economic determinants of institutional holdings, we show that over the two-year period 2005–2006 institutional ownership increases by more than 4 percent and the number of institutional investors increases by almost ten for mandatory IFRS adopters, relative to non-adopters. Results are consistent for different analyses based on annual firm-level as well as quarterly firm-level and country-level changes in institutional holdings. Second, we document that the positive IFRS effects on institutional holdings are concentrated among investors whose orientation and styles suggest they are most likely to benefit from higher quality financial statements. For example, institutional holdings in mandatory IFRS adopters increase significantly for active investors, but changes are much lower or insignificant for passive investors. Similarly, IFRS-related holdings increases are substantially higher for value and growth investors than for index and income investors. Finally, we document that the increases in institutional holdings associated with IFRS are not homogeneous across countries. Our findings indicate that institutional holdings increase for first-time mandatory adopters primarily in countries in which enforcement and reporting incentives are strongest, and where the differences between local GAAP and IFRS are relatively high. Inferences are unaffected by various sensitivity tests, including different sample definitions and additional control variables.

Our paper is most closely related to Bradshaw et al. (2004) and Covrig et al. (2007). Bradshaw et al. (2004) is the first study to show that institutional stock ownership is related to firm-level accounting choices, although they do not consider the role of accounting standards. Covrig et al. (2007) show that stock ownership by foreign mutual funds increases with the voluntary adoption of International Accounting Standards (IAS) by non-U.S. firms. Our paper extends this line of research by investigating the effects of mandatory IFRS adoption on institutional holdings. Our paper is also related to two concurrent studies reporting that foreign mutual fund ownership increases following mandatory IFRS introduction (Yu 2010; DeFond et al. 2011). However, both of those studies focus on the mechanisms through which IFRS attracts foreign investors. Yu (2010) examines the IFRS effects of lower information asymmetry, measured primarily by the accounting distance between the investees' and investors' accounting standards. DeFond et al. (2011) examine the IFRS effects of increased comparability based on the similarity of accounting standards of investee firms within industries and across different countries.

We contribute to the literature in several ways. First, we provide evidence that institutional investor decisions respond to IFRS reporting. This helps to explain the mechanism through which the IFRS-related capital market outcomes reported in Daske et al. (2008) and Li (2010) occur. Second, we employ a research design that enhances our ability to link the observed ownership effects to the financial reporting regime change and helps rule out alternative explanations (Daske et al. 2008, 1132) as follows: (1) we identify the timing of changes in institutional holdings relative to first-time IFRS reporting events; (2) we examine the institutional holdings effects of mandatory IFRS adoption with reference to differences in the predicted demand for and use of financial reporting information by different investors; and (3) we focus on changes in holdings rather than levels of holdings, thereby helping to control for firm- and country-level characteristics that determine holdings independently of the financial reporting regime. Our focus on mandatory IFRS adoption helps to mitigate potential issues of selection bias and omitted correlated factors in voluntary adoption studies (Leuz and Wysocki 2008).

Finally, we introduce a new research design in examining the institutional context of IFRS reporting effects. Our approach is different from that of prior work (Daske et al. 2008; Li 2010) because we test the impact of complementary institutional features by using a single model based on institutional "bundles" rather than several models focusing on different institutional characteristics. Our findings on the role of institutions contribute to a growing literature highlighting that the introduction of higher quality accounting standards is necessary, but not sufficient, for higher quality financial reporting and associated benefits (Li 2010).

The remainder of the paper is organized as follows. In the next section we discuss prior related studies and elaborate on the motivation of our study. In Section III we describe in detail the research design and data. We discuss our findings in Section IV. Finally, in Section V we present our conclusions.

II. THEORETICAL BACKGROUND AND MOTIVATION

Proponents of IFRS claim that IFRS have advantages over local accounting standards in many countries for several reasons. First, IFRS may be more capital-oriented and, therefore, more useful to investors (Hail et al. 2010). Second, IFRS can reduce the choice of accounting methods, thus constraining managerial discretion (International Accounting Standards Board [IASB] 1989; Ashbaugh and Pincus 2001; Barth et al. 2008). Third, IFRS require accounting measurements and recognition that better reflect a firm's underlying economic position, hence providing more relevant information for investment decisions (IASB 1989; Barth et al. 2008). Fourth, IFRS increase required disclosures, thereby mitigating information asymmetries between firms and their shareholders (Leuz and Verrecchia 2000; Ashbaugh and Pincus 2001). Aside from the higher financial reporting quality argument, proponents of IFRS also claim that harmonization around IFRS increases comparability of firms across markets and countries, hence facilitating cross-border investment and integration of capital markets (Armstrong et al. 2010; DeFond et al. 2011).

In light of these potential advantages, advocates of IFRS often argue that they can be beneficial for investors, issuers, and economies because enhanced financial reporting can result in increased investor demand for equities and lower cost of capital (European Council 2002). Theory suggests that these outcomes will follow if (1) market liquidity increases and price protection falls due to lower information asymmetries among investors (Baiman and Verrecchia 1996; Verrecchia 2001); (2) risk sharing improves due to increased awareness of investment opportunities by investors (Merton 1987; Easley and O'Hara 2004); or (3) the estimation risk facing investors falls (Jorgensen and Kirschenheiter 2003; Lambert et al. 2007; Hughes et al. 2007). In each case investment and portfolio decisions depend on financial reporting, and a change to a higher quality and homogeneous financial reporting regime is predicted to result in an increase in demand for equities and investment holdings.

On the other hand, there are several reasons why the expected benefits of IFRS can be questioned. First, reducing accounting alternatives may result in a less true and faithful representation of the firm's underlying economics (Barth et al. 2008). Second, increasing managerial flexibility, because of the principles-based nature of IFRS, may augment the opportunity for earnings management (Barth et al. 2008). Third, and perhaps most importantly, an increasing number of scholars emphasize that dysfunctional reporting incentives combined with weak enforcement mechanisms can reduce financial reporting quality, even when high-quality accounting standards are implemented (Ball et al. 2003; Burgstahler et al. 2006; Ball 2006).

To the extent that financial reporting under IFRS enhances the quality and comparability of accounting information provided by issuers, we predict that mandatory IFRS adoption is associated with an increase in the demand for equity in IFRS adopting firms. We also predict that IFRS-related changes in holdings are more likely to be observed for investors whose investment orientations and styles rely most heavily on firm-specific financial information (Bushee and Goodman 2007).

The expected effects of mandatory IFRS adoption are likely to depend on the institutions of the adopting country (Hail et al. 2010). In line with this argument, Daske et al. (2008) and Li (2010) document that the capital market effects of IFRS are more pronounced in countries with stricter enforcement regimes and therefore better IFRS implementation; stronger reporting incentives and therefore higher quality financial reporting; and higher divergence between IFRS and local GAAP and therefore a larger change of domestic accounting rules.[1] Accordingly, we predict that the IFRS-related effects on institutional holdings for first-time mandatory adopters are likely to be greater in countries with higher quality institutions and countries with less conformity between domestic GAAP and IFRS.

III. RESEARCH DESIGN AND DATA DESCRIPTION

Identification Strategies

An important concern in studies of the impact of institutional change is to provide evidence that observed effects reflect causality and rule out alternative explanations. Our baseline results, using a difference-in-differences research design similar to Daske et al. (2008), document increases in institutional holdings after mandatory IFRS adoption. Our main challenge is to develop convincing evidence that increases in institutional holdings result directly from the financial reporting regime change and are not due to other contemporaneous regulatory or market changes affecting IFRS countries. Our research design includes two strategies designed to address this challenge.

Our first strategy uses information on the timing of firm-specific IFRS reporting to infer whether causality runs from financial reporting to institutional holdings changes. Therefore, we examine changes in holdings for annual and quarterly periods relative to first-time IFRS reporting events. Our tests include both firm-level as well as country-quarter analysis similar to the country-month analysis of Daske et al. (2008).[2]

In the second set of tests, we use investor type and investor style as instruments reflecting investor demand for, and use of, financial reporting information. Investor type is defined as active or passive. Active investors often use firm-specific information, including financial reporting numbers and disclosures, to determine the portfolio weights of individual stocks. In contrast, passive investors do not seek to take security-specific views and rely on decision rules that do not depend on financial reporting information. Thus, we predict that institutional holdings changes will be more significant for active investors than for passive investors if institutional holdings changes are causally linked to the financial reporting regime change.

---

[1] We note, however, that Francis et al. (2009) provide evidence suggesting that an improved information environment enhances asset allocation, irrespective of a country's legal regime and enforcement mechanisms. Also, in a related study Daske et al. (2011) document that "serious" mandatory IFRS adopters experience higher liquidity and lower cost of capital compared to "label" adopters, providing evidence on the firm-level heterogeneity in the capital market effects of IFRS adoption.

[2] We conduct country-quarter analysis rather than country-month analysis because our institutional ownership data is published at the end of each calendar quarter.

Similarly, within the subset of active investors, some investors have investment styles that are more dependent on accounting numbers than others (Bushee and Goodman 2007). Our holdings data allow us to identify several common stock-oriented investment styles including value, growth, index, and income investing. Value investors seek to determine whether stock market values are fairly priced relative to fundamental values estimated using firm-specific accounting numbers, and take long (short) positions relative to their benchmark in under-valued (over-valued) stocks. Growth investors seek to forecast future value-relevant outcomes that will determine future capital gains, for example by identifying stocks with above-average earnings growth potential. Financial statements and forward-looking disclosures are important inputs to the decision models of many such investors. In contrast, income investors usually focus on short-term dividends and dividend yield, while index investors invest in proportion to stock index weights. In the latter two investment styles, financial statement information is less important in investment decisions. Therefore, we predict that changes in institutional holdings attributable to the IFRS regime change are more likely to be observed for value and growth investors than for income and index investors.

Our empirical tests progressively build evidence consistent with causality running from IFRS adoption to changes in institutional holdings. First, we conduct firm-level analysis based on different annual measurement periods relative to first-time IFRS reporting events. Then, we perform additional firm-level analysis using quarterly changes in institutional holdings. Next, we conduct analysis at the country-quarter level. Finally, we examine how annual changes in institutional holdings depend on investor demand for financial reporting information, reflected in investor orientation and style.

Firm-Level Annual and Quarterly Analyses

The firm-level analyses employ a difference-in-differences design similar to Daske et al. (2008), utilizing data on both voluntary and mandatory adopters of IFRS in countries where IFRS are mandated (treatment sample firms) and non-IFRS adopters in other countries (benchmark sample firms), and using versions of the following model:

$$\begin{aligned}\Delta \mathit{Institutional\ Holdings} = {} & \delta_0 + \delta_1 \mathit{First\text{-}Time\ Mandatory} + \delta_2 \mathit{Voluntary} \\ & + \delta_3 \mathit{Voluntary{*}Mandatory} + \Sigma\gamma_j \Delta \mathit{Controls}_j + \varepsilon. \end{aligned} \tag{1}$$

For the annual firm-level analysis *ΔInstitutional Holdings* is the change in an institutional holdings proxy over a year. The marginal effects of IFRS reporting on institutional holdings are captured by three binary indicator variables *First-Time Mandatory*, *Voluntary*, and *Mandatory * Voluntary*, coded based on the reporting standards used in each firm-year (Worldscope code WS07536). *First-Time Mandatory* refers to observations for firms that never reported under IFRS before mandatory adoption and equals 1 for all firm-years with IFRS reporting periods ending on or after the local mandated IFRS adoption date (i.e., December 31, 2005), and 0 otherwise. It captures the extent to which institutional holdings of first-time mandatory adopters are different after IFRS adoption. *Voluntary* relates to observations for firms that voluntarily switched to IFRS reporting before it was mandated and equals 1 for all firm-years with IFRS reporting by voluntary adopters, and 0 otherwise. It captures the extent to which institutional holdings are different for firms that voluntarily adopt IFRS. *Voluntary * Mandatory* equals 1 for all voluntary adopter firm-years ending on or after the mandated local IFRS adoption date, and 0 otherwise. It captures the extent to which institutional holdings of voluntary IFRS adopters are different in the mandatory IFRS period.

Focusing on changes in institutional holdings in Equation (1) enables us to develop insights about the timing of any changes in institutional ownership relative to firm-level IFRS adoption events, as discussed below. The changes model also provides more powerful tests, given that a firm serves as its own control because both current-year and prior-year levels data are required to be included in the changes sample. This requirement helps alleviate concerns that unmodeled factors other than IFRS adoption, including possible database selection biases, could explain differences in the levels of institutional holdings between treatment and benchmark samples, and across time, thus increasing confidence that documented results reflect causality running from the IFRS reporting regime change.

Our baseline analysis of Equation (1) involves measuring changes in institutional holdings over calendar-year intervals. In this case the IFRS indicator coefficient estimates capture the average annual IFRS effects over the two-year period 2005–2006. Since holdings changes are measured over identical periods for both treatment and benchmark samples, the calendar-year approach controls effectively for unmodeled factors affecting both treatment and benchmark samples. However, to ensure that our inferences are not sensitive to the measurement interval for holdings changes, we also report results based on two alternative annual windows spanning firms' fiscal year-ends. The window labeled −2/+2 measures holdings changes over the last two quarters of a fiscal year and the first two quarters of the next fiscal year, while the annual window labeled −1/+3 measures changes over the last quarter of a fiscal year and the first three quarters of the next fiscal year. A possible advantage of examining changes over these alternative windows is that IFRS information contained in annual financial statements becomes available to investors during the measurement interval. However, a significant disadvantage of the alternative windows is that heterogeneity in fiscal year-end dates within and across the treatment and benchmark samples may lead to weaker control for unmodeled factors. Hence, our baseline calendar-year results could be viewed as more conservative estimates of overall IFRS effects that better control for unmodeled global factors underlying holdings changes.

Having established our baseline results using annual windows, we use versions of Equation (1) to address the identification problem by allowing the coefficients on *First-Time Mandatory* and *Voluntary* $*$ *Mandatory* to depend on the arrival of firm-specific IFRS information within the mandated IFRS adoption period. Specifically, we conduct firm-quarter analysis by re-estimating Equation (1) using institutional holdings changes measured over quarterly intervals. We supplement Equation (1) by adding indicator variables that capture incremental reporting-time effects during the mandated IFRS period 2005–2006. Incremental holdings changes for first-time mandatory adopters are captured by indicator variables $\mathit{First\text{-}Time\ Mandatory}_q$ ($q = -2, -1, +1, +2, +3$) set equal to 1 in quarter q and 0 in other quarters, using the convention that $q = -1$ is the quarter of the fiscal year-end and $q = +1$ is the quarter following the fiscal year-end.[3] The coefficients on *Voluntary* $*$ $\mathit{Mandatory}_q$ capture incremental reporting-time holdings changes for voluntary adopters in the mandatory IFRS period in a similar manner.

While financial reporting lags vary across countries, we believe that it is reasonable to expect that financial statements will usually be released late in quarter +1 or early in quarter +2.[4] Therefore, we predict incremental investor reaction to financial statement information in quarter +2 and significantly positive coefficients of $\mathit{First\text{-}Time\ Mandatory}_{+2}$. Delayed response to financial statement information will be indicated if the coefficients on $\mathit{First\text{-}Time\ Mandatory}_{+3}$ are significant. We predict that incremental holdings changes in quarter +3 (if any) will be lower in magnitude than those in quarter +2. If firms report earlier and investors react to information in annual financial statements within quarter +1, then $First\text{-}Time\ Mandatory_{+1}$ will also be positive. If firms do not report sufficiently early in quarter +1 for investors to react in the same quarter, then $First\text{-}Time\ Mandatory_{+1}$ will capture any anticipation effects, as will the coefficients on $First\text{-}Time\ Mandatory_q$ ($q = -2,-1$). The interpretation of the coefficients on the reporting-time indicator variables $Voluntary * Mandatory_q$ is similar, with $Voluntary * Mandatory_{+2}$ being most likely to capture investor reaction to financial statement information.

---

[3] For example, for firms where the first-time IFRS fiscal period ends in December 2005, $\mathit{First\text{-}Time\ Mandatory}_{+1}$ is set equal to 1 for the first quarter of 2006, while $\mathit{First\text{-}Time\ Mandatory}_{-1}$ equals 1 in the fourth quarter of 2005.

[4] DeFond et al. (2007) report considerable variation in earnings announcement dates, with the median of country-level median earnings reporting lags being 83.25 days. Annual reports containing full financial statements are likely to follow at least several weeks later, depending on statutory reporting rules.

Country-Quarter Analysis

We also conduct country-level analysis relating aggregate changes in institutional holdings to changes in an index tracking the actual rate of reporting under IFRS in each country. The research design follows closely the country-month analysis of Daske et al. (2008). We estimate the following regression pooled over countries and quarters:

$$\Delta Institutional\ Holdings = \delta_0 + \delta_1 \Delta IFRS\ Adoption\ Rate + \Sigma\gamma_j Controls_j + \mu. \qquad (2)$$

In Equation (2) *ΔInstitutional Holdings* is the change in the median institutional holdings in a country-quarter and *ΔIFRS Adoption Rate* is the change in an index of cumulative IFRS adoption within a country based on the publication of mandatory IFRS financial statements and measured in two ways described below. Consistent with the firm-quarter analysis, we predict that *ΔIFRS Adoption Rate* will be associated with changes in institutional holdings with a one-quarter lag, reflecting the time taken for institutional investors to process information and rebalance portfolios.

We construct the IFRS adoption rate index for a country in two ways. First, we define IFRS adoption with reference only to the reporting of first-time IFRS annual financial statements. In this case and in line with the firm-quarter analysis, we assume that financial statement publication occurs in the quarter following the fiscal year-end. We assign a firm-level adoption counter a value of 1 starting in the quarter following the first-time IFRS fiscal year-end. In each calendar-quarter *IFRS Adoption Rate* is the average value of the firm-level adoption counter for the set of mandatory adopters in the country. The index has a maximum value of 1 in the quarter when the final firm in a country reports under IFRS for the first time. Similar to Daske et al. (2008), we label the index based on annual financial reporting as $IFRS\ Adoption\ Rate_{FYE}$.

If IFRS information arrives as a result of quarterly or interim announcements during the IFRS adoption year, then $IFRS\ Adoption\ Rate_{FYE}$ may understate the true rate of cumulative IFRS information arrival in the first-time adoption year and overstate the true rate in the following year. To address this possibility we also construct the *IFRS Adoption Rate* index with reference to quarterly, interim, and annual earnings announcement dates (Worldscope item WS05905), assuming that quarterly or interim financial reporting is under IFRS in the mandatory adoption year. Under this definition of the *IFRS Adoption Rate* index, in the quarter of an announcement we increase the firm-level adoption counter value by $1/n$, where n equals 4, 2, or 1 for quarterly, semi-annual interim, and annual announcements, respectively.[5] In each calendar-quarter *IFRS Adoption Rate* is the average value of the firm-level adoption counter for the set of mandatory adopters in the country. The index has a maximum value of 2 in the quarter when the final firm in a country reports annual financial statements under IFRS for the first time, having previously reported quarterly or interim statements. Similar to Daske et al. (2008), we label this variable $IFRS\ Adoption\ RATE_{INTERIM}$.

---

[5] In some countries firms vary in the frequency of reporting. For example, some U.K. firms voluntarily report quarterly while being required to report semi-annual interim financial statements. Therefore, we define the firm-level reporting frequency for a given year (n) by counting the actual number of announcements reported by each firm in the year.

The Role of Institutions

We analyze the institutional context of IFRS financial reporting effects using a new approach. Our approach is similar to Daske et al. (2008) and Li (2010) in that we model IFRS effects conditional on proxies for the likelihood of high-quality enforcement and application of IFRS, and measures of accounting difference between local GAAP and IFRS. Our approach is different because we estimate the impact of complementary institutional features in a single model; we also use measures of accounting difference capturing the changes in accounting that can be expected when moving from an issuer's local GAAP to IFRS.

Collinearity between institutional proxies may arise because different institutions in a country do not develop independently and they can complement one another. This perspective predicts that institutional "bundles" will emerge (Wysocki 2011). This is confirmed by Leuz et al. (2003) and Leuz (2010) who apply cluster analysis to institutional proxies that capture the strength of securities regulation, legal enforcement, investor protection, disclosure, and transparency of reporting practices. We classify countries into three clusters defined in Leuz (2010) and characterized as outsider economies with strong outsider protection and legal enforcement (*Cluster 1*); insider economies with stronger rule enforcement (*Cluster 2*); and insider economies with weaker rule enforcement (*Cluster 3*).[6] We then allow the IFRS effects captured by *First-Time Mandatory*, *Voluntary*, and *Voluntary* $*$ *Mandatory* to vary across clusters. We predict that IFRS-related holdings changes for first-time mandatory adopters are likely to be more pronounced in the cases of *Clusters 1* and *2* because reporting incentives and enforcement are predicted to lead to higher quality reporting.

We consider whether IFRS-related changes in institutional holdings depend on the extent of accounting change involved in moving from local GAAP to IFRS reporting. We do not model the dependence of institutional holdings on country-pair differences between an investor's home country GAAP and an issuer's home country GAAP (Yu 2010). Rather we examine how the differences between local GAAP and IFRS influence changes in institutional holdings generally. Holding reporting incentives and enforcement constant, the mandatory switch to IFRS in countries with large differences between domestic accounting standards and IFRS should result in larger improvements in financial reporting quality and in comparability, to the benefit of all institutional investors irrespective of their location.

We estimate accounting differences using the two distinct measures proposed by Ding et al. (2005, 2007), who analyze a comprehensive set of 111 accounting items reported in the *GAAP 2001* survey of national accounting rules conducted by seven large auditing firms. *Absence* captures missing local GAAP financial reporting rules relative to IFRS. *Divergence* captures inconsistencies between local GAAP and IFRS treatments. Ding et al. (2007) show that these two dimensions are uncorrelated and argue that they cannot be considered as substitutes or complements. *Absence* implies an accounting issue is not important enough in a specific jurisdiction and/or is beyond the standard-setter's competence, while *Divergence* means the issue is important in the country and the standard-setter is competent and confident enough to adopt a non-IAS approach (Ding et al. 2009, 160).[7] We believe that the Ding et al. (2005, 2007) measures are appropriate in our research setting for four main reasons. First, our focus is on the IFRS-related ownership effects across institutional investors irrespective of their location. The *Absence* and *Divergence* measures capture the potential accounting changes that can benefit investors generally. Second, the Ding et al. (2005, 2007) measures are based on a comprehensive list of potential discrepancies. Third, the distinction between absence and divergence could be important.[8] Fourth, empirical evidence in Garcia Osma and Pope (2011) indicates that *Divergence* explains country-level adjustments to local GAAP numbers on first-time IFRS adoption, whereas alternative measures of accounting difference do not or they have the wrong sign.

---

[6] Consistent with institutions being associated with financial reporting quality, Leuz (2010) reports higher disclosure and more informative earnings in *Cluster 1* relative to *Cluster 2*, and in *Cluster 2* relative to *Cluster 3*.

[7] *Divergence* may also indicate that the national GAAP covered a particular issue before it was covered by IAS.

We predict that IFRS-related changes in institutional holdings for first-time mandatory adopters will be positively related to *Divergence* and *Absence* if differences between alternative accounting regimes are important to investors. To implement these measures in empirical tests we generate binary indicators from the *Divergence* and *Absence* continuous variables using the medians across IFRS adoption countries as the classification cut-off.

Empirical Proxies

Institutional Holdings

In contrast to previous and concurrent research that focuses on the ownership of mutual funds (Covrig et al. 2007; Yu 2010; DeFond et al. 2011), this is the first study to examine the links between IFRS reporting and global institutional ownership including investors other than mutual funds. Our institutional holdings data are drawn from the Thomson Financial Ownership (TFO) quarterly data feed and include domestic and foreign holdings of mutual funds, pension funds, insurance companies, hedge funds, private equity funds, and venture capital funds from 45 countries.[9] An advantage of our data is that the data capture a much higher proportion of total institutional ownership. For example, we document average ownership of almost 22 percent, in contrast to Covrig et al. (2007), Yu (2010), and DeFond et al. (2011) who report a mean value of mutual fund ownership between 2 percent and 10 percent. Under the assumption that decisions by non-mutual fund institutional owners reflect informed investor opinion, the expanded scope of our institutional investor universe enhances the power of our tests to detect IFRS-related effects.[10]

---

[8] Based on the same data source, Bae et al. (2008) propose two measures (*gaapdif1* and *gaapdif2*) of differences in accounting standards at the country-pair level. Moreover, these measures are a blend of absence of local GAAP rules and divergence between local GAAP and IAS and they are not intended to provide a comprehensive catalogue of country-level differences from IAS. Bae et al. (2008) construct country scores based on differences relating to 21 (*gaapdiff1*) or 52 (*gaapdiff2*) "key" accounting items, selected because they appear in the past research literature (*gaapdiff1*) and because they appear frequently in the survey. The focus on country-pairs restricts the set of accounting rules considered because countries that differ from IFRS are also required to have similar GAAP. As a consequence, relative to *Absence* and *Divergence*, the Bae et al. (2008) measures are expected to be noisy measures of the distance between local GAAP and IAS for two reasons. First, they exclude some important sources of differences. For example, *gaapdiff1* excludes 12 standards in IAS, 11 of which affect recognition and measurement, including IAS 39 (*Financial Instruments*), where *Divergence* is often high and accounts for 6 out of the 111 items considered by Ding et al. (2005, 2007). Second, *gaapdiff1* also covers two standards (IAS 1, *Presentation of Financial Statements*, and IAS 24, *Related Party Disclosures*) where there is a high degree of local GAAP conformity with IAS (81 percent and 73 percent, respectively). The *gaapdiff1* measure with respect to these two items captures *Absence* only. We thank an anonymous reviewer for helpful comments on the relative merits of the alternative measures of accounting difference.

[9] Thomson Reuters state that the database includes holdings on more than 44,000 global equity issues. The source of the data depends on the region. Specifically, in the case of Europe, Middle East, Africa, South/Central America, and Asia, information on equity holdings is processed primarily from *Shareholder*, *Trade*, and *Mutual Fund Portfolio Reports*, which gather data from annual and interim reports, stock exchanges, regulatory bodies, investor relations departments, and third-party vendors. In the case of U.K. and Ireland holdings, data above a 0.015 percent threshold is sourced from inspection of firms' registers of shareholders. In the case of the U.S., security information is gathered from SEC 13D, 13G, 10K, 20F, and 13F filings and from mutual fund and pension fund portfolio reports.

To obtain our holdings proxies we employ the following procedures. First, we retrieve disaggregated holdings data on the number and value of institutional shares from the Historical Holdings Files for each quarter in the period 2003–2007. Second, using the Historical Security File we identify all types of common and registered equity securities owned by institutional investors for each firm. ADR holdings are converted to the equivalent number of shares of the underlying equity class by multiplying ADR holdings by the ADR-underlying conversion ratio. From this file we also collect data on various items including share price, outstanding shares, and security identifiers. Finally, we retrieve data on investor orientation (active or passive) and investor style (value, growth, income, and index) from the Historical Owner File.

In line with prior studies of institutional ownership we consider the aggregate percentage ownership of institutional shareholders (Covrig et al. 2007; DeFond et al. 2011) and the total number of institutional investors (O'Brien and Bhushan 1990; Walther 1997; Bradshaw et al. 2004). Percentage ownership is calculated as the total market value of shares owned by institutional investors (or investors having particular orientations or style) divided by the total market value of the firm at the end of a quarter. The number of institutional investors is the count of investors with recorded holdings at the end of a quarter.

Control Variables

Following prior literature (Leuz et al. 2010; DeFond et al. 2011), we include control variables documented to be associated with institutional holdings: *Nanalysts* (the number of analysts at the fiscal year-end from I/B/E/S) to proxy for richness of the information environment; *Market Index* (Worldscope item WS05661), a dummy variable that equals 1 if the firm is included in any national stock market index and *MSCI Index*, a binary variable set equal to 1 if the firm is included in the MSCI World Index, to control for the firm's visibility to investors;[11] *ADR* (WS11496), a dummy that takes the value of 1 if the firm has an ADR listed on a U.S. exchange, to proxy for the degree of visibility and information environment richness of non-U.S. firms; *Big4* (WS07800), a dichotomous variable equal to 1 if the firm is audited by a Big 4 firm or their predecessors, to control for investor preferences for auditors with a strong reputation; *Size* (WS07210), defined as the natural logarithm of market value of equity in U.S. dollars at year-end, to proxy for liquidity, information environment, and fiduciary concerns; *ROE*, measured as net income before extraordinary items (WS01551) divided by total assets at the beginning of the year (WS02999), to control for accounting performance; *RET*, calculated as log of (RI_{t+1}/RI_t), where RI is the DataStream Total Return Index on first January, to capture the effect of stock market performance over the fiscal year; *RetVar*, measured as the standard deviation of monthly stock returns over the fiscal year, to control for firm risk.

In addition, we include in our set of controls a number of proxies for firm fundamentals that are potentially related to institutional holdings, namely *Dividend Yield*, computed as total dividends

---

[10] Further, mutual fund investment decisions are partially driven by (retail) customer funds flows and, therefore, mutual fund ownership changes reflect effects related to private investor sentiment and liquidity needs. In contrast, many of the non-mutual fund investors in our database are longer-term investors, e.g., pension funds and insurance companies, whose investment decisions are less susceptible to swings in private investor sentiment and liquidity.

[11] *Market Index* is available as a Worldscope data item, but is time-invariant and available for the most recent year of our study, i.e., 2006. *MSCI Index* is available on a time-varying basis. We thank Old Mutual Asset Management for providing these data.

(WS05376) divided by market value of equity at year-end (WS08001); *Book-Market*, defined as book value of equity (WS03501) divided by market value of equity at year-end (WS08001); *Earnings-Price*, calculated as net income (WS01551) divided by market value of equity at year-end (WS08001); and *Leverage*, defined as total liabilities (WS03351) divided by total assets at year-end (WS02999). Following Daske et al. (2008), we also include *US GAAP* (WS07536), a dummy variable equal to 1 if a non-U.S. firm prepares its financial statements according to U.S. financial reporting rules, and *Market Benchmark*, calculated as the yearly mean of the dependent variable from all observations in the benchmark sample. The latter variable is used to help us disentangle the IFRS effects from effects due to changes in the general economic conditions or changes in institutional holdings unrelated to IFRS reporting. All continuous variables are winsorized at the extreme 1 percentiles.

To perform the firm-quarter analysis, we incorporate in Equation (1) only those control variables that can be measured at the end of a quarter, i.e., *Size*, *Ret*, *RetVar*, and *Market Benchmark*. In the country-quarter analysis based on Equation (2) we include the natural logarithm of *Market Value* (WS08001), measured as stock price times the number of shares outstanding (in U.S. dollars) at the end of quarter *q*–3; *Return Variability*, defined as the standard deviation of the previous 12 monthly stock returns measured at time *q*–3; *Market Benchmark*, defined as the mean dependent value from all observations in the benchmark sample; and the level and the change in the dependent variables measured at time *q*–3.

Sample and Descriptive Statistics

We include all listed firms in the Worldscope database in the period 2003–2006 with complete data for the independent variables and for which ownership data are available in the TFO database.[12] For firms that adopt IFRS for fiscal years ending December 2005, this sample period allows us to compare changes in institutional holdings in the year prior to mandatory IFRS adoption, the transition year, and the year after first-time adoption. Applying these criteria yields a sample of 35,160 firm-years for 10,852 unique firms and 45 countries. Table 1 describes the sample composition across years and countries. Panel A indicates that 9.61 percent (4.92 percent) of firm-years in the overall sample are mandatory (voluntary) IFRS adopters. Mandatory IFRS reporters represent 14.15 percent (21.93 percent) of sample observations for fiscal years ending in 2005 (2006), indicating that a substantial number of firms adopt IFRS for the first time for fiscal years ending in 2006 rather than 2005. Panel B of Table 1 shows the country composition of the IFRS treatment sample, which includes 11,926 observations from 3,865 firms and 24 countries, and the benchmark sample, which comprises 23,234 firm-year observations from 6,987 firms and 21 countries.[13] As in prior studies adopting a similar sampling frame, the U.S. accounts for approximately 43 percent of benchmark sample observations. We test whether our main results are sensitive to the weight of the U.S. in the benchmark sample in robustness checks.

Table 2 describes the institutional holdings variables. Panel A reveals that over the full

---

[12] We constrain the sample to end in 2006 because extending the sample period beyond 2006 would increase the risk that any observed changes in institutional holdings in treatment firms relative to benchmark firms are due to factors other than IFRS adoption.

[13] The apparent discrepancy between the 3,380 total IFRS mandatory adopters reported in Panel A and the 3,865 total treatment firms reported in Panel B is due to some treatment countries not requiring IFRS reporting by all listed companies, e.g., because, the firms do not report consolidated financial statements. Singapore is excluded from our sample because it mandated adoption of IFRS in 2003, in contrast to all other countries in our treatment sample where the adoption date was 2005.

TABLE 1

IFRS Adoption by Year and Sample Composition by Country

Panel A: IFRS Adoption for Full Sample by Year

		First-Time Mandatory Adopters		*Voluntary* Adopters	
Year	**Total Firm-Years**	**Firm-Years**	**Percent**	**Firm-Years**	**Percent**
2003	8,385	0	0.00	458	5.46
2004	8,364	0	0.00	468	5.60
2005	8,450	1,196	14.15	399	4.72

U.K.	743	2,424			
Total	3,865	11,926	Total	6,987	23,234

The complete sample consists of a maximum 35,160 firm-year observations from 45 countries during the period 2003–2006 with sufficient institutional holdings data from TFO and financial data from Worldscope to perform the regression analysis. We exclude countries with less than 20 firm-year observations.

Panel A reports descriptive information for the following indicators: (1) *First-Time Mandatory* that refers to observations of firms that never reported under IFRS before mandatory adoption and equals 1 for all firm-years with IFRS reporting periods ending on or after the local mandated IFRS adoption date (i.e., December 31, 2005), and 0 otherwise; and (2) *Voluntary* that relates to observations of firms that voluntarily switched to IFRS reporting before it was mandated and equals 1 for all firm-years with IFRS reporting by voluntary adopters, and 0 otherwise.

Panel B reports the number of firms and firm-years for: (1) the treatment sample, i.e., countries that mandated IFRS reporting and (2) the benchmark sample, i.e., countries that do not allow or do not require IFRS reporting.

Value	34,330	18.30	4.00	39.44
Income	34,330	2.38	0.00	7.67
Index	34,330	6.53	0.00	11.03

The complete sample consists of a maximum 35,160 firm-year observations from 45 countries during the period 2003–2006 with sufficient institutional holdings data from TFO and financial data from Worldscope to perform the regression analysis. *Percentage Ownership* is defined as the total market value of shares owned by institutions divided by the total market value of the firm at year-end, where both items are measured in U.S. dollars. *Number of Investors* refers to the total number of institutional investors of the firm at year-end. Δ denotes changes in variables computed over year *t*–1 to *t*. Additional descriptive information is provided conditioning on: (1) Investment Orientation, i.e., active versus passive investors and (2) Investment Style, i.e., value/growth versus index/income investors.

sample mean (median) institutional ownership is 21.69 percent (6.93 percent) of issued equity and the mean (median) number of institutional shareholders is 74.88 (18.00). The changes in both institutional holdings proxies are, on average, positive over the sample period. Panels B and C provide insights to the importance of different investor types in our data. Most firms have active institutional investors—on average there are 63.72 active investors owning 18.62 percent of equity. In contrast, passive investors have lower overall equity stakes than active investors and are fewer in number—on average 11.16 passive investors own equity stakes totaling 3.22 percent of equity. Analysis of investment styles reveals that growth and value investors hold stakes in a large proportion of sample firm-years and holdings are economically significant. For example, value investors hold mean equity stakes of 5.94 percent.

TABLE 3

Descriptive Statistics of Independent Variables

Variable (n = 35,160)	Mean	Median	Std. Dev.

The complete sample consists of a maximum 35,160 firm-year observations from 45 countries during the period 2003–2006 with sufficient institutional holdings data from TFO and financial data from Worldscope to perform the regression analysis.
All financial variables are winsorized at the 1st and 99th percentiles.

Variable Definitions:
Size = the natural logarithm of market value of equity in U.S. dollars;
ROE = net income before extraordinary items divided by total assets at the beginning of the year;
RET = log of (RI_{t+1}/RI_t), where *RI* stands for Return Index on January 1st;
RetVar = standard deviation of monthly stock returns over the fiscal year;
Leverage = total liabilities divided by total assets;
Dividend Yield = total dividends divided by market value of equity;
Book-Market = book value of equity divided by market value of equity;
Earnings-Price = net income divided by market value of equity;
Nanalysts = number of analysts;
Big4 = dichotomous variable equal to 1 if the firm is audited by a Big 4 auditing firm or their predecessors, and 0 otherwise;
MSCI Index = binary variable equals 1 if the firm is included in the MSCI World Index, and 0 otherwise;
Market Index = dummy variable equals 1 if the firm is part of any stock market index, and 0 otherwise;
ADR = dummy that takes the value of 1 if the firm has an ADR listed on a U.S. exchange, and 0 otherwise; and
US GAAP = dummy variable equal to 1 if a non-U.S. firm prepares its financial statements according to the U.S. financial reporting rules, and 0 otherwise.

Table 3 describes the control variables used in our regression tests and Table 4 shows the correlations between the independent variables. Descriptive statistics are pooled over the full sample. The data do not suggest any unusual behavior.[14]

IV. EMPIRICAL RESULTS

In this section we discuss our empirical findings. First, we report univariate difference-in-differences results, followed by baseline regression results capturing the average effects of

---

[14] Untabulated findings document low correlations among the institutional factors employed in our cross-section analysis, *Absence*, *Divergence*, and *Cluster 1* and *Cluster 2* indicators.

The complete sample consists of a maximum 35,160 firm-year observations from 45 countries during the period 2003–2006 with sufficient institutional holdings data from TFO and financial data from Worldscope to perform the regression analysis.

Pearson's correlation coefficients between independent variables are reported. All financial variables are winsorized at the 1st and 99th percentiles. For variable definitions see Tables 1 and 3.

IFRS adoption on holdings changes measured over different annual windows. Second, we provide further analysis showing that changes in institutional holdings are concentrated in the first quarter after first-time mandatory IFRS reporting. Third, we present results of the country-quarter analysis. Fourth, we report additional findings on the IFRS-related ownership effects across different types of investors. Fifth, we discuss results on the dependence between IFRS-related holdings changes and country-level institutional factors capturing reporting incentives, compliance, and accounting differences. Finally, we describe a series of additional tests and robustness checks.

TABLE 5

Difference-in-Differences Analyses of Ownership

	(0.000)	(0.000)	(0.000)	(0.038)	(0.000)

The complete sample consists of a maximum 35,160 firm-year observations from 45 countries during the period 2003–2006 with sufficient institutional holdings data from TFO and financial data from Worldscope to perform the regression analysis.

Panels A and B report results from difference-in-differences analysis of the IFRS-related ownership effects; p-values in parentheses.

Percentage Ownership is defined as the total market value of shares owned by institutions divided by the total market value of the firm at year-end, where both items are measured in U.S. dollars. *Number of Investors* refers to the total number of institutional investors of the firm at year-end. Δ denotes changes in variables computed over year $t-1$ to t. The treatment sample consists of countries that mandated IFRS reporting and the benchmark sample includes countries that do not allow or do not require IFRS reporting. The pre-IFRS period refers to changes in 2004, while the transition period and the post-IFRS period relate to changes over 2005 and 2006, respectively.

Difference-in-Differences Analysis

Table 5 presents difference-in-differences analyses showing the contrast between institutional holdings changes for the treatment and benchmark samples over the pre-IFRS period (2004), the IFRS adoption year (2005) and the post-IFRS period (2006). We report results for changes in our two institutional holdings proxies, *Percentage Ownership* and *Number of Investors*.

The differences between treatment sample and benchmark sample holdings changes in the bottom row of each panel indicate that changes in institutional holdings are significantly higher in the benchmark sample in the pre-IFRS year and the transition year for both holdings proxies. In contrast, institutional holdings changes in the post-IFRS year are significantly higher in the treatment sample. Both panels reveal that institutional holdings grow over the sample period for both the treatment and the benchmark samples. Mean changes in percentage ownership and number of investors are uniformly positive for all sample periods. However, the final two columns indicate that differences in percentage ownership changes are significant only in the post-IFRS period. Results for the change in the number of investors indicate relatively large increases in the post-IFRS period and a small increase in the IFRS implementation year relative to the pre-IFRS year. The observation that benchmark sample holdings also increase in the post-IFRS period emphasizes the importance of controlling for common global factors underpinning institutional holdings changes.

The difference-in-differences results at the bottom right-hand side of each panel indicate that treatment sample firms have statistically and economically significantly higher holdings changes in the post-IFRS period compared to benchmark sample firms. These results provide the first evidence that mandatory IFRS reporting has a positive impact on institutional holdings. We now examine whether coincident changes in other determinants of institutional holdings can explain the IFRS reporting effects.

Baseline Findings

Table 6 presents the results of estimating Equation (1) for the full sample. These and subsequent regression results are estimated with industry-year fixed effects captured by indicator variables using the industry classifications in Campbell (1996), country dummy variables based on Worldscope nation code (WS06027), and White standard errors adjusted to account for correlation within firm clusters (Rogers 1994; Petersen 2009).

In Table 6, Panel A the changes in institutional holdings proxies are measured over calendar-year intervals, where the mandatory IFRS period is defined as 2005 and 2006. Hence, the estimated coefficients on *First-Time Mandatory* and *Voluntary * Mandatory* capture average effects over the two-year period. Empirical findings indicate that there is an increase in average institutional ownership of 2.2 percent per annum for first-time mandatory IFRS adopters, after controlling for global changes affecting benchmark sample firms and changes in other firm-level determinants of institutional ownership. Similarly, the number of investors in mandatory IFRS adopters increases by nearly five relative to benchmark firms in the IFRS adoption period. The positive coefficient on *Voluntary * Mandatory* suggests that voluntary adopters also experience an increase in institutional holdings at the time of mandated adoption. This result is in line with Yu (2010) and with the liquidity effects for voluntary adopters at the time of mandated adoption reported by Daske et al. (2008). A possible explanation is that voluntary adopters also benefit from increased comparability when IFRS is mandated (Daske et al. 2008; DeFond et al. 2011).

In Table 6, Panel B the changes in institutional holdings are measured over different annual intervals ordered relative to the fiscal year-end of each firm. Results for both alternative windows −2/+2 and −1/+3 are consistent with those in Panel A, indicating statistically and economically significant ownership effects for first-time mandatory IFRS adopters. *First-Time Mandatory* and *Voluntary * Mandatory* coefficient estimates for both holdings proxies are higher for the −2/+2 interval than for the calendar-year intervals. However, the R^2 statistics are considerably lower for both alternative windows, suggesting that this research design does not control as effectively for unmodeled factors.

Firm-Quarter Analysis

The results in Table 6 capture the average institutional holdings effects associated with IFRS reporting measured over annual intervals. To alleviate concerns that these results could reflect factors other than IFRS reporting, we now examine the timing of institutional ownership changes

TABLE 6

No. Countries	45	45	45	45
Adj. R^2	6.8%	5.5%	10.8%	7.7%

The complete sample consists of a maximum 35,160 firm-year observations from 45 countries during the period 2003–2006 with sufficient institutional holdings data from TFO and financial data from Worldscope to perform the regression analysis.

Panel A refers to the base model, where institutional holdings are measured at the end of each calendar year.

Panel B refers to two alternative annual windows: in models 1 and 3 holdings changes are measured over the last two quarters of a fiscal year and the first two quarters of the next fiscal year; in models 2 and 4 holdings changes are measured over the final quarter of a fiscal year and the first three quarters of the next fiscal year.

Financial variables are winsorized at the 1st and 99th percentiles. All models are estimated with White standard errors adjusted to account for correlation within firm clusters; p-values in parentheses. For all other control variable definitions see Table 3.

Variable Definitions:

Percentage Ownership = total market value of shares owned by institutions divided by the total market value at firm-year level, where both items are measured in U.S. dollars;

Number of Investors = total number of institutional investors at firm-year level;

Δ = changes in variables computed over year $t-1$ to t;

First-Time Mandatory = observations of firms that never reported under IFRS before mandatory adoption and equals 1 for all firm-years with IFRS reporting periods ending on or after the local mandated IFRS adoption date (i.e., December 31, 2005), and 0 otherwise;

Voluntary = observations of firms that voluntarily switched to IFRS reporting before it was mandated and equals 1 for all firm-years with IFRS reporting by voluntary adopters, and 0 otherwise; and

*Voluntary * Mandatory* = 1 for all voluntary adopter firm-years ending on or after the mandated local IFRS adoption date, and 0 otherwise.

during 2005–2006 by isolating incremental changes over the quarters spanning firms' fiscal year-end dates. Results are reported in Table 7.

The significant positive coefficients on *First-Time Mandatory* and *Voluntary * Mandatory* indicate that, on average, changes in institutional holdings are positive over the eight quarters in the mandatory IFRS period. However, the incremental reporting-time coefficients indicate that changes in holdings also depend on annual financial reporting events. Significant fractions of the IFRS-related holdings changes for first-time mandatory adopters reported in Table 6 are concentrated in quarter +2, the quarter after the release of most IFRS financial statements. For example, the coefficient on $First\text{-}Time\ Mandatory_{+2}$ for percentage ownership indicates an average incremental ownership change in quarter +2 of 1.4 percent. In contrast, incremental changes in holdings for first-time mandatory firms in other quarters before and after the release of annual financial

The sample in models 1 and 2 consists of a maximum 85,741 and 89,368 firm-quarter observations, respectively, from 45 countries during the period 2003–2006 with sufficient institutional holdings data from TFO and financial data from Worldscope to perform the regression analysis.

(continued on next page)

TABLE 7 (continued)

Financial variables are winsorized at the 1st and 99th percentiles. All models are estimated with White standard errors adjusted to account for correlation within firm clusters; p-values in parentheses. For all other control variable definitions see Table 3.

Variable Definitions:
Percentage Ownership = total market value of shares owned by institutions divided by the total market value of the firm at the end of a quarter, where both items are measured in U.S. dollars;
Number of Investors = total number of institutional investors at firm-quarter level;
Δ = changes in variables computed over quarter $q-1$ to q;
First-Time Mandatory = observations of firms that never reported under IFRS before mandatory adoption and equals 1 for all firm-years with IFRS reporting periods ending on or after the local mandated IFRS adoption date (i.e., December 31, 2005), and 0 otherwise;
Voluntary = observations of firms that voluntarily switched to IFRS reporting before it was mandated and equals 1 for all firm-years with IFRS reporting by voluntary adopters, and 0 otherwise;
*Voluntary * Mandatory* = 1 for all voluntary adopter firm-years ending on or after the mandated local IFRS adoption date, and 0 otherwise; and
$First\text{-}Time\ Mandatory_q$ ($q = -2, -1, +1, +2, +3$) = 1 in quarter q and 0 in other quarters, using the convention that $q = -1$ is the quarter of the fiscal year-end and $q = +1$ is the quarter following the fiscal year-end. The indicator variables $Voluntary * Mandatory_q$ are defined in an exactly analogous manner to $First\text{-}Time\ Mandatory_q$.

statements are generally small in economic terms, and with three exceptions, statistically insignificant.[15]

The coefficients on $Voluntary * Mandatory_{+2}$ indicate that the incremental holding changes for voluntary adopters in quarter +2 are also positive and significant in economic terms, again accounting for a large fraction of the overall change documented for voluntary adopters in the mandated IFRS period. However, in contrast to the results for mandatory adopters, incremental holdings changes for voluntary adopters in the three prior quarters −2, −1, and +1 are significantly negative, implying that institutional holdings in these firms fall in the quarters leading up to the mandating of IFRS for other firms and suggesting that holdings changes follow different dynamics for voluntary compared to first-time adopters. Overall, the results in Table 7 provide reassurance that the main results reported in Table 6 are associated with financial reporting events in the mandatory IFRS period.

Country-Quarter Analysis

We now report the results of the country-quarter analysis, based on Equation (2). In this analysis we run regressions of the quarterly aggregate change in median institutional holdings in a country on the change in the adoption rate in that country in the previous quarter. In the first analysis we estimate the adoption rate index assuming that first-time adoption occurs by the end of the quarter following the fiscal year-end of first-time adoption ($IFRS\ Adoption\ Rate_{FYE}$). We can measure changes in this variable over five quarters (four quarters in 2006 and the first quarter in 2007), yielding 120 country-quarter observations over the 24 treatment countries. In the second analysis we base the adoption rate index on actual annual, interim, and quarterly announcement dates ($IFRS\ Adoption\ Rate_{INTERIM}$). We can measure changes in this variable over nine quarters (four quarters in each of 2005 and 2006 and the first quarter of 2007) yielding 216 country-quarter observations over the 24 treatment countries. Panel A of Table 8 reports descriptive statistics for

---

[15] The sum of the $First\text{-}Time\ Mandatory_q$ coefficients in Table 7 closely reconcile with the *First-Time Mandatory* coefficient in Table 6. From Table 7 the estimated total holdings change over the two-year period 2005–2006 is $8 \times First\text{-}Time\ Mandatory + \Sigma_q First\text{-}Time\ Mandatory_q$, giving 0.037 (10.07) for percentage ownership (number of investors). The equivalent estimated changes from Table 6 over the two years equal to $2 \times First\text{-}Time\ Mandatory$, giving 0.044 (9.876) for the above two holdings proxies, respectively.

The sample in models 1 and 3 consist of a maximum 120 country-quarter observations from 24 treatment sample countries during a five-quarter period, where mandatory IFRS annual reports become initially available (i.e., from January 2006 to March 2007). The sample in models 2 and 4 consists of a maximum 216 country-quarter observations

(continued on next page)

TABLE 8 (continued)

during a nine-quarter period (i.e., we extend the above window by four quarters, from January 2006 to March 2008, in order to allow for interim reporting effects). We include only firms that report under IFRS for the first time in the year IFRS become mandatory.

Panel A reports descriptive statistics for the dependent and independent variables during the above two periods.

Panel B reports the coefficient estimates of regressions of country-level change in institutional holdings on the change in the country-level IFRS adoption rate.

We aggregate all firm-level variables in a given country and quarter by computing medians. All models are estimated with White standard errors; p-values in parentheses.

Variable Definitions:
Δ*Percentage Ownership* (Δ*Number of Investors*) = quarterly change in the median percentage ownership (number of investors) in a country;
Δ*IFRS Adoption Rate* = quarterly change in the cumulative index of IFRS adoption for a country;
Market Value = stock price times the number of shares outstanding (in U.S. dollars) at the end of quarter Q–3;
Return Variability = standard deviation of the previous 12 monthly stock returns measured at time Q–3;
Market Benchmark = mean dependent value from all observations in the benchmark sample. We include lagged level and change in the dependent variable measured at time Q–3; and
Δ = changes in variables computed over quarter Q–1 to Q.

both country-quarter samples for the aggregate changes in percentage ownership and number of investors, for changes in adoption rates and for control variables.

Inferences from the two adoption rate estimation methodologies are identical. Table 8, Panel B shows that both changes in aggregate percentage ownership and changes in aggregate numbers of investors are positively and significantly related to changes in IFRS adoption rates occurring in the previous quarter. For example, in the case of percentage ownership the coefficient of *IFRS Adoption Rate*$_{FYE}$ is 0.042 and has a p-value of 0.002, and in the case of the number of investors the estimate of *IFRS Adoption Rate*$_{INTERIM}$ is 12.58 and has a p-value of 0.000 (see models 1 and 4, respectively). The results suggest that investors respond in their portfolio investment decisions to IFRS financial statement information as it becomes available.

It might appear from Panel B that *IFRS Adoption Rate*$_{FYE}$ is more powerful at capturing variation in aggregate holdings changes than *IFRS Adoption Rate*$_{INTERIM}$ because the R^2 statistics are higher. However, results in models 1 and 3 are not directly comparable with those in models 2 and 4 because *IFRS Adoption Rate*$_{INTERIM}$ is estimated over four additional quarters in 2005. In untabulated tests we also estimate models 2 and 4 over the shorter five-quarter period with 120 observations. When we do this, R^2 statistics increase to 52.4 percent and 14.7 percent and the coefficients on the change in the adoption rate are 0.0421 and 11.27, respectively. Thus, results for the two adoption rate indices are qualitatively similar.

Overall, these country-quarter results reflect evidence that changes in the information environment associated with adoption of IFRS within countries are associated with increases in institutional investor holdings.

Investor Orientation and Style Analysis

Next we examine whether IFRS effects on institutional holdings are concentrated among the investors most likely to make use of financial statement information in investment decisions. Since results for the different annual intervals are robust to the selection of measurement interval, we report results for tests using the calendar-year intervals.

Table 9 presents results partitioned by investment orientation, where we decompose holdings into active and passive investors; and by investment style where we decompose holdings into growth, value, index, and income investors. Panel A contains results for changes in percentage ownership and Panel B for changes in the number of institutional investors. Consistent with our predictions we find that mandatory IFRS adoption is associated with significant increases in the

Adj. R^2	17.6%	16.8%	16.7%	13.0%	19.8%	7.0%

The complete sample consists of a maximum 35,160 firm-year observations from 45 countries during the period 2003–2006 with sufficient institutional holdings data from TFO and financial data from Worldscope to perform the regression analysis. The sample is partitioned by investment orientation, i.e., active versus passive investors and by investment style, i.e., growth/value versus index/income investors.

All models are estimated with White standard errors adjusted to account for correlation within firm clusters; p-values in parentheses. Financial variables are winsorized at the 1st and 99th percentiles. For all other control variable definitions see Table 3.

Variable Definitions:

Percentage Ownership = total market value of shares owned by institutions divided by the total market value of the firm at year-end, where both items are measured in U.S. dollars;

Number of Investors = total number of institutional investors of the firm at year-end;

Δ = changes in variables computed over year *t*–1 to *t*;

First-Time Mandatory = observations of firms that never reported under IFRS before mandatory adoption and equals 1 for all firm-years with IFRS reporting periods ending on or after the local mandated IFRS adoption date (i.e., December 31, 2005), and 0 otherwise;

(continued on next page)

TABLE 9 (continued)

Voluntary = observations of firms that voluntarily switched to IFRS reporting before it was mandated and equals 1 for all firm-years with IFRS reporting by voluntary adopters, and 0 otherwise; and
Voluntary $*$ *Mandatory* = 1 for all voluntary adopter firm-years ending on or after the mandated local IFRS adoption date, and 0 otherwise.

percentage ownership of active investors, but not of passive investors. The coefficient on *First-Time Mandatory* for ownership of active investors (0.023) is almost identical to the coefficient obtained for overall ownership in Panel A of Table 6, while the coefficient in the model for passive investor is close to zero. These results suggest that IFRS-related ownership increases are attributable to active investors. The *First-Time Mandatory* results for investor style are also consistent with predictions. They indicate that ownership changes are very similar and significant for value and growth investors, who are predicted to make more use of financial statements in their investment decision processes. In contrast, changes in ownership by index and income investors do not appear to be related to first-time mandatory adoption.

Results for changes in the number of investors in Table 9, Panel B are consistent with our findings for percentage ownership in indicating strong IFRS first-time adoption effects for active investors, and value and growth investors. The main difference between results in Panel B is that the average number of passive investors also increases with mandatory IFRS adoption. However, while the coefficient on *First-Time Mandatory* in the case of passive investors is 0.758, the average first-time adoption increase for active investors is almost six times as high, with a coefficient of 4.185. Similarly, the investor style results show that the average first-time mandatory adoption increase in the number of index investors is less than half the increase for growth and value investors, while the corresponding increase in the average number of income investors is statistically insignificant. Empirical findings are similar for voluntary adopters.

Overall, we document that the positive institutional holdings effects associated with mandatory IFRS adoption are not present across all types of investors. Specifically, we find that the ownership effects are considerably stronger for active and, in particular, value and growth investors, i.e., for investors who depend to a greater extent on financial statement information. These results are consistent with institutional holdings responding to common and higher quality financial reporting when financial statement numbers are important in investment decision making.

Cross-Country Analysis

We now examine whether changes in institutional holdings in response to mandatory IFRS adoption depend on enforcement and financial reporting incentives as well as on differences between local GAAP and IFRS. Our empirical tests condition the estimated IFRS effects on indicator variables representing the country clusters of Leuz et al. (2003) and Leuz (2010) and on the two measures of accounting difference in Ding et al. (2005, 2007), namely *Divergence* and *Absence*.

Panel A in Table 10 describes the institutional variables. Note that four (eight) treatment (benchmark) countries are dropped from this analysis because the institutional data are not available, but the overall number of observations lost is low because they are not large countries. Panel B shows the results of paired t-tests of differences in the means of institutional clusters and accounting divergence measures across the 20 treatment sample countries and the 13 benchmark sample countries, revealing no significant differences in institutional characteristics between the two samples.

No. Countries	33	33
R^2	13.1%	18.7%

The complete sample consists of a maximum 35,160 firm-year observations from 45 countries during the period 2003–2006 with sufficient institutional holdings data from TFO and financial data from Worldscope to perform the regression analysis.

Panel A reports raw values of the institutional factor scores for the treatment and benchmark sample countries, respectively. The treatment sample consists of countries that mandated IFRS reporting and the benchmark sample includes countries that do not allow or do not require IFRS reporting. Cluster classification is based on legal regulation quality, enforcement, and reporting practices variables and is taken from Leuz (2010), characterized as outsider economies with strong outsider protection and legal enforcement (*Cluster 1*); insider economies with stronger rule enforcement (*Cluster 2*); and insider economies with weaker rule enforcement (*Cluster 3*). *Absence* and *Divergence* are drawn from Ding et al. (2007); higher values represent more missing rules/disclosures from local GAAP and more differences between IFRS and local GAAP, respectively. We transform continuous values of *Divergence* and *Absence* into binary variables (in parentheses) splitting by the median of treatment sample countries; coded 1 = above median, and 0 otherwise.

Panel B shows differences in mean institutional factor scores between benchmark and treatment countries (only for countries with all available scores); p-values in parentheses for (ii) – (i).

Panel C reports coefficient estimates of the cross-country regression analysis; p-values in parentheses.

All models are estimated with White standard errors adjusted to account for correlation within firm clusters. Financial variables are winsorized at the 1st and 99th percentiles. For all other control variable definitions see Table 3.

Variable Definitions:

Percentage Ownership = total market value of shares owned by institutions divided by the total market value of the firm at year-end, where both items are measured in U.S. dollars;

Number of Investors = total number of institutional investors of the firm at year-end;

Δ = changes in variables computed over year $t-1$ to t;

First-Time Mandatory = observations of firms that never reported under IFRS before mandatory adoption and equals 1 for all firm-years with IFRS reporting periods ending on or after the local mandated IFRS adoption date (i.e., December 31, 2005), and 0 otherwise;

Voluntary = observations of firms that voluntarily switched to IFRS reporting before it was mandated and equals 1 for all firm-years with IFRS reporting by voluntary adopters, and 0 otherwise; and

*Voluntary * Mandatory* = 1 for all voluntary adopter firm-years ending on or after the mandated local IFRS adoption date, and 0 otherwise.

Empirical findings in Panel C of Table 10 are very consistent across the two institutional holdings change proxies.[16] They reveal large differences in the marginal IFRS effects across country clusters and between countries with high accounting divergence. The *First-Time Mandatory* main effect coefficient is significantly negative for both changes in ownership (–0.044) and changes in the number of investors (–9.348), indicating that *Cluster 3* first-time adoption firms with small accounting differences experience a relative decline in institutional holdings. The incremental coefficients of first-time mandatory adoption are positive for both *Cluster 1* and *Cluster 2* countries. The marginal first-time mandatory effects of accounting differences, as measured by *Divergence*, on institutional holdings are also significantly positive, suggesting that IFRS-induced changes in financial statement numbers are larger for firms in countries where accounting divergence is greater. In contrast, *Absence* is insignificant when interacted with *First-Time Mandatory*, in line with arguments that the absence of rules might imply that some accounting issues are not important in some jurisdictions. While we do not have predictions for the conditioning effects of institutional variables on *Voluntary* $*$ *Mandatory*, results also reveal differences in effects across clusters for changes in ownership percentage, but not in the number of investors. *Absence* and *Divergence* are less relevant for these firms, probably because they already report under IFRS.[17]

To sum up, results suggest that the impact of the mandatory introduction of IFRS on the investment decisions of institutions varies significantly across countries. In particular, in line with our predictions and consistent with capital market outcomes documented in prior studies (Daske et al. 2008; Li 2010), results indicate that the positive effects of mandatory IFRS adoption on institutional holdings are found primarily in countries with strong institutions.[18] Moreover, where there is high divergence between domestic GAAP and IFRS, the impact of mandatory IFRS introduction on institutional holdings is even higher.

Additional Analysis

We expand our empirical analysis by performing two additional tests. First, we repeat the analysis in Table 6 separately for emerging and developed market countries. This analysis can provide further reassurance that earlier results are not driven by flows of funds into developed markets due to unmodeled factors, e.g., other institutional features that affect market microstructure across sample countries.[19] Second, current research indicates that other recent EU market regulations affect market liquidity and the cost of capital (Christensen et al. 2011). To address concerns that positive institutional holdings effects are driven by other EU regulatory changes we estimate all models in Table 6 after excluding EU members. Untabulated results indicate that when institutional holdings change proxies are measured over calendar-year intervals, mandatory financial reporting under IFRS is associated with increased ownership only for developed countries. However, when we employ alternative annual measurement windows as in Panel B of Table 6, we find evidence of positive and significant mandatory IFRS effects for both emerging and developed countries. Similarly, we document positive and significant IFRS effects on institutional ownership for the −1/+3 and −2/+2 intervals but not for the calendar-year interval when focusing on non-EU countries.[20]

---

[16] We also include main effects for the institutional variables to allow for the possibility that institutional holdings changes depend directly on the country context in which investment takes place. The *First-Time Mandatory*, *Voluntary*, and *Voluntary* $*$ *Mandatory* main effects can be interpreted as the IFRS effects applicable to countries belonging to *Cluster 3* when accounting *Divergence* and *Absence* are low.

[17] We note that the coefficient on *Voluntary* $*$ *Mandatory* $*$ *Divergence* is negative in the case of changes in the number of investors. As discussed in the context of Table 7 results, the dynamics of holdings changes for voluntary adopters appear to be complex.

[18] Covrig et al. (2007) find that institutional ownership increases on voluntary IFRS adoption for firms with low-quality information environments. If *Clusters 1* and *2* are regarded as conducive to higher quality information environments, then our results on institutional effects might appear to contradict Covrig et al. (2007). However, analysis reveals that the institutional variables underlying the clusters are not significantly correlated with the firm-level proxy for information environment quality employed by Covrig et al. (2007), i.e., *Number of Analysts* $*$ *Size*. We interpret this as indicating that the institutional clusters capture different characteristics of firms' environments. When we repeat the Covrig et al. (2007) analysis using their firm-level proxy, we confirm their result.

[19] To identify emerging markets we use the *Standard & Poor's and International Finance Corporation of World Bank* (S&P/IFC) emerging market index (Li and Hoyer-Ellefsen 2008). Accordingly, our sample includes 20 emerging and 21 developed countries; four countries (Hong Kong, Luxemburg, Bermuda, and Taiwan) are not classified.

Sensitivity Tests

To test the robustness of the baseline empirical findings reported in Table 6 we perform a number of sensitivity tests. First, we employ alternative samples, as follows: (1) we limit the sample to IFRS adoption countries only; (2) we define a benchmark sample to include a maximum of 150 randomly selected firms per country; (3) we exclude U.S. firms from the benchmark sample; (4) we limit the benchmark sample to U.S. firms; (5) we hold sample composition constant over time; (6) we exclude from the treatment sample firms that did not switch to IFRS in the sample period; and (7) we limit the treatment sample to EU countries. We also include the following additional control variables: (1) the total number of shares outstanding at year-end (WS05301) to proxy for new equity issuance (Bradshaw et al. 2004); (2) the ADR indicator in levels rather than in changes, given that the latter variable is dropped from the regressions due to lack of variability; and (3) the percentage of closely held shares (WS08021) to capture the effect of ownership structure and free float (Leuz et al. 2010).

We then examine the possibility that the changes in institutional holdings we observe are driven by the IFRS-related changes in liquidity documented by Daske et al. (2008). We test whether liquidity changes account for changes in investor holdings by introducing exogenous controls for liquidity changes, defining liquidity as the Amihud (2002) illiquidity measure, the bid-ask spread, and the frequency of zero returns, and by modeling the liquidity controls as endogenously determined, using market value, share turnover, return variability, a binary indicator controlling for U.S. GAAP reporting, and a market benchmark as first-stage instruments for liquidity.

To provide reassurance that our results are not driven by growth in the number of institutional investors and their holdings over time, we also restrict the analysis to holdings by institutional investors for whom we observe data in both the pre- and post-IFRS periods.

Since some of our control variables depend on accounting measurement rules, their use in the pre- and post-IFRS periods could introduce noise or bias into the analysis. Noise will reduce the likelihood of finding statistically significant results, but bias threatens the conclusions drawn from the analysis if any bias is correlated with the IFRS indicators and institutional investment in the pre-mandatory adoption period. To help address this concern, we interact the three IFRS indicators with all accounting-based control variables (i.e., *ROE*, *Leverage*, *Dividend Yield*, *Book-Market*, and *Earnings-Price*).

---

[20] The sensitivity of annual window results is likely driven by heterogeneity in the timing of the annual financial reporting cycles across sample firms. For example, in the case of developed countries, the percentage of the treatment sample firm-years having a December fiscal year-end is considerably higher than for the benchmark sample (i.e., 68 percent compared to 46 percent). However, this relation is reversed in the case of emerging market countries where the proportion of treatment (benchmark) sample firm-years having December fiscal year-ends is 61 percent (80 percent).

Finally, we repeat our cross-country analysis after incorporating *Divergence* in continuous form. This helps mitigate concerns regarding the clustering of this dummy variable where a number of countries with only slightly different divergence scores are coded differently.[21]

When we implement each of these sensitivity tests we find that all the main empirical findings and inferences in Table 6 are qualitatively identical to those reported in the paper.

V. CONCLUSIONS

Based on annual and quarterly firm-level analyses and quarterly country-level tests we report evidence of economically significant increases in institutional holdings in mandatory IFRS adopters. After first-time IFRS reporting, institutional ownership and the number of investors increase for mandatory IFRS adopters relative to a benchmark sample of non-adopters. We also show that increases in institutional holdings are concentrated among investors whose investment orientation and styles rely more heavily on financial statement information. This raises confidence that the holdings effects we observe are driven by the financial reporting regime change, and not by changes in unmodeled factors that might also determine institutional investment. In further analysis we document that the positive impact of mandatory IFRS adoption on institutional holdings is restricted to countries where enforcement and reporting incentives are strong and where divergence between local accounting standards and IFRS is relatively high.

Our study is subject to several caveats that might suggest avenues for future research. First, while our research is designed to address the identification problem, we cannot rule out entirely the possibility that other concurrent regulatory or economic changes affect IFRS adoption countries, but they would have to be related to the financial reporting cycle and affect only certain investor types within those countries. Second, our findings suggest that voluntary adopters also experience an increase in institutional holdings following the mandating of IFRS. Moreover, there are potentially interesting differences in patterns of holdings changes for first-time mandatory and voluntary adopters in relation to both the financial reporting cycle and the role of accounting differences. It is possible that our results for voluntary adopters reflect comparability externalities after mandatory IFRS adoption by other peers. However, our evidence does not shed direct light on the validity of this conjecture. Future work could address the challenge of identifying comparability effects in international settings. Finally, we do not investigate the supply side of the increase in institutional holdings in first-time IFRS adopters. Further work might investigate the extent to which institutional ownership changes are associated with reductions in holdings of investors who are not captured by our data, e.g., insiders and family block-holders, and with secondary equity offerings and capital restructuring programs that increase the supply of equity.

Overall, our study helps shed new light on the channels underpinning the capital market effects of IFRS adoption reported in Daske et al. (2008) and Li (2010). The evidence supports the argument that IFRS adoption is beneficial for institutional investors and issuers of securities.

An Analysis of Multiple Consecutive Years of Material Weaknesses in Internal Control

Lawrence A. Gordon
University of Maryland

Amanda L. Wilford
Southern Utah University

ABSTRACT: The primary objective of the current study is to empirically reexamine the relation between material weaknesses in internal control (MW) and cost of equity (CE). We direct particular emphasis to the way non-remediation, as well as remediation, of MW affects a firm's CE. This study utilizes a dataset that contains a large sample of second-year MW non-remediation cases, as well as third-, fourth-, and fifth-year non-remediation cases. The findings provide evidence that reporting MW, absent any remediation, in multiple consecutive years has a significant negative impact on CE. However, the current study also shows that the market views favorably a reduction in the number of MW (i.e., partial remediation). Our study helps to reconcile conflicting results in the literature devoted to the relation between MW and CE.

Keywords: *internal control; monitoring; remediation; material weaknesses; cost of equity.*

I. INTRODUCTION

The corporate scandals in the United States around the turn of the 21st century (e.g., Enron, WorldCom, Tyco, etc.) culminated in the passage of the Sarbanes-Oxley Act of 2002 (SOX). This Act requires firms to report material weaknesses in internal control (hereafter, MW) related to the reliability of financial reporting to the Securities and Exchange Commission (SEC). The SOX reporting requirements have given rise to a plethora of research, much of which

has focused on the impact of MW on a firm's cost of equity (hereafter, CE).[1] For example, Ashbaugh-Skaife et al. (2009; hereafter, ACKL) find a significant positive relation between MW (reported under SOX Sections 302 and 404) and CE. In contrast, Ogneva et al. (2007; hereafter OSR) find no significant relation between MW (reported under SOX Section 404) and CE. The above research recognizes the potential impact of remediation of MW on CE, but the time periods covered in previous studies encompass, at most, the initial two consecutive years of regulated reporting. Furthermore, previous studies have not considered the impact of the number of reported MW on the relation between CE and remediation.

The primary objective of the current study is to reexamine the relation between MW and CE. We direct particular emphasis to examining the way non-remediation of MW in multiple consecutive years affects CE, as well as the impact of remediation of MW on CE. We utilize a dataset that contains a large sample of second-year MW non-remediation cases, as well as third-, fourth-, and fifth-year non-remediation cases. Thus, this study differentiates between firms that report MW in only one year and firms that report MW in two or more consecutive years. The current study also considers the number of MW in each year, as well as the specific types of MW. As such, this study extends earlier studies that consider the potential impact of MW and remediation (or lack thereof) on a firm's CE.

Our findings offer three important contributions to the existing literature. First, they indicate that MW reported in multiple consecutive years have a progressively larger and statistically significant negative impact on CE when firms that partially remediate are excluded from the sample. That is, the market notices that some firms are slow to remediate MW, whereas other firms take timely remediation steps to address MW. Second, our study shows that the number and specific types of MW are significant factors in understanding the relation between MW and CE. In fact, even if a firm does not remediate all MW in a given year, the market views favorably a reduction in the number of MW (i.e., partial remediation). Third, given the richness of the dataset, the current study helps to reconcile conflicting results in the prior literature on the effects of MW.

II. BACKGROUND AND HYPOTHESES

Background

The value of SOX Section 404 has been debated within private and public circles since its passage (e.g., see Ernst & Young 2005; U.S. House of Representatives 2005). Most recently, the Dodd-Frank Wall Street Reform and Consumer Protection Act of 2010 ordered an additional investigation into the costs versus the benefits of Section 404 (U.S. House of Representatives 2010). Recent internal control research has used evidence from SOX Sections 302 and 404 to examine the impact of MW on CE. For example, OSR do not find evidence that a higher CE is associated with reporting SOX Section 404 MW, after controlling for firm characteristics and predicted analyst forecast error. Consistent with the results posited by OSR, Beneish et al. (2008) also find no significant relation between SOX Section 404 MW and CE. However, Beneish et al. (2008) do find a significant and positive relation between SOX Section 302 MW and CE. In contrast to the research noted above, ACKL find a significant and positive relation between SOX Sections 302 and 404 MW and CE. ACKL note that their model's risk integration, along with sample-selection procedures, differentiates their model and results from the model used and the results obtained by OSR.

---

[1] Although not the focus of this study, researchers have also examined the impact of reporting MW on stock price (e.g., see Gupta and Nayar 2007; Beneish et al. 2008; Hammersley et al. 2008; Kim and Park 2009).

Key distinctions exist between Sections 302 and 404 of SOX. That is, Section 302 is a quarterly internal control disclosure assessment under which managers are required to recognize and report MW. Section 404 is an annual internal control assessment that requires management to report MW. Additionally, Section 404 requires accelerated filers to obtain an audit opinion attesting to the results of management's internal control system assessment.[2] Given the points cited above, the current study focuses upon disclosures of MW related to SOX Section 404. However, in reconciling conflicts in the prior literature, we also consider SOX Section 302 MW.

Previous studies that examine the relation between MW and CE cover time periods extending no longer than two years. Thus, the previously cited studies use only a two-year sample period when considering remediation of MW. Nevertheless, prior research considers the remediation of MW, if that remediation occurs within the subsequent reporting period. For example, OSR account for remediation of Section 404 MW if the remediation occurs within the time period of November 2004 through January 2006. OSR (2007, 1272) find "little evidence that firms that remediate their internal control weaknesses have lower cost of equity." Beneish et al. (2008) also account for remediation of MW and do not find that such remediation significantly benefits firms through a lower CE. In contrast, ACKL (2009, 5) find "clear evidence ... that firms reporting effective internal controls or firms remediating previously disclosed ICDs [internal control deficiencies] benefit through lower cost of equity." The above points notwithstanding, remediation of MW was not the focus in earlier studies, nor could it have been given the time periods covered in these studies.

The current study focuses upon remediation of MW using an expanded dataset that considers MW in multiple consecutive years, reported under SOX Section 404, spanning a six-year time period (i.e., 2004–2009). We focus on remediation because taking timely remediation actions, with respect to MW, is an essential part (or at least should be an essential part) of a firm's internal control system.

Material Weaknesses and Cost of Equity

A firm that reports SOX Section 404 MW sends an explicit signal to market participants that the reliability of its accounting disclosures is less than desirable. Intuitively, this signal likely leads investors to apply a higher risk premium to their discounting of the firm's expected cash flows. That is, investors will likely demand a higher expected return from a firm reporting MW than they would from a similar firm that does not report MW. Demand for a higher expected return essentially equates to a higher CE.

Lambert et al. (2007) provide theoretical justification for the above intuition, outlining a theoretical framework that shows that the quality of accounting information disclosures affects CE via its impact on a firm's risk. This impact is the result of both direct and indirect effects. The direct effect on CE is the result of the market assessment of the covariance of the firm's cash flows with the cash flows of other firms in the market. The indirect effect on CE is the result of the effect of accounting information disclosure quality on a firm's real economic decisions, which, in turn, has an impact on the firm's expected value and the covariance of the firm's cash flows with cash flows of other firms in the market.

---

[2] An accelerated filer is defined by the SEC as "(1) the issuer had an aggregate market value of voting and non-voting common equity held by non-affiliates of the issuer of $75 million or more, as of the last business day of the issuer's most recently completed second fiscal quarter; (2) the issuer had been subject to the reporting requirements of Section 13(a) or 15(d) of the Exchange Act [15 U.S.C. 78m(a) or 78o(d)] for a period of at least 12 calendar months; (3) the issuer previously had filed at least one annual report; and (4) the issuer was not eligible to use Forms 10-KSB and 10-QSB [17 CFR 249.310b and 17 CFR 249.308b] for its annual and quarterly reports" (SEC 2005).

In general, Lambert et al. (2007) show that higher (lower) quality accounting information disclosures can lower (raise) CE. In discussing the direct effect, they note "that higher quality accounting information and financial disclosures . . . unambiguously [move] a firm's cost of capital closer to the risk-free rate. Moreover, this effect is not diversifiable" (Lambert et al. 2007, 387). Although the indirect effects are more ambiguous, they too could clearly lead to a negative relation between the quality of accounting information disclosures and CE.

Building on the theoretical work of Lambert et al. (2007) and Easley and O'Hara (2004), as well as the empirical work of Francis et al. (2004, 2005), OSR argue that firms with MW are likely to have a higher CE due to higher information risk associated with these firms. Additionally, OSR (2007, 1256) determine that these firms are likely to be impacted by the fact that MW reflect poor management controls "which could increase business risk and the cost of equity." Building largely on the Lambert et al. (2007) framework, ACKL (2009, 7) argue that "the quality of a firm's internal control over financial reporting affects investors' assessment of firm risk and cost of capital because if a firm has weak internal control, then the quality or precision of its accounting signals is impaired." ACKL (2009, 7) then go on to predict that firms with MW "exhibit higher idiosyncratic risk, systematic (beta) risk, and higher cost of equity relative to firms with strong internal control."

In sum, there is reason to expect that MW negatively affect CE. Furthermore, it seems logical to assume that, as the number of multiple consecutive periods in which MW are disclosed increases, the severity of the negative effect increases. Of course, whether a negative relation between MW and CE actually exists is an empirical issue. As noted above, the empirical evidence to date is mixed.

Hypotheses

Based on the above discussions, considering MW and the remediation of MW over several years should provide a greater understanding of the impact of MW on CE than considering a single year of MW reporting. Whereas some firms are quick to take timely corrective actions in response to MW, other firms are slow to remediate and have reported MW in two, three, or more consecutive years. Thus, while firms that report MW in a single year may experience a negative impact on their CE, reporting MW in multiple consecutive years acts as a clear signal to the market that the firms in question are not effectively remediating their MW. This reasoning leads to the following two general hypotheses (stated in the alternative form):

H1: Disclosing MW within a particular year will have a negative effect on a firm's CE (i.e., higher CE).

H2: Disclosing MW within multiple consecutive years will have a larger negative effect on the CE for those firms making such disclosures than for firms that do not report MW in multiple consecutive years.

As a corollary to H2, we also test H3 below (stated in the alternative form):

H3: The greater the number of multiple consecutive years in which MW are disclosed, the larger the negative effect on the CE for those firms making such disclosures.

H2 and H3 imply that firms either fully remediate or do not remediate all of their MW from one year to the next. However, it is possible that firms reporting MW in multiple consecutive years may have remediated a portion (as opposed to all) of their MW. In this latter case, one would expect to empirically observe a reduction in CE as a result of these firms' partial remediation of their MW. This assumption leads to a fourth hypothesis (stated in the alternative form):

H4: Partial remediation of MW, within a particular year, will have a positive effect on a firm's CE (i.e., lower CE).

As will be discussed further in Section IV, to test H2 and H3 independent of H4 in the multivariate analyses, we first analyze the data in terms of firms that do not partially remediate their MW from one year to the next.[3] This analysis is followed by an analysis that includes all firms (i.e., including firms that do partially remediate their MW).

III. DESIGN OF STUDY

Sample

We draw our sample from the Audit Analytics database, which includes all SOX Section 404 auditor assessment reports (24,806) filed with the SEC during the time period of November 2004 (the effective date for accelerated filers reporting under Section 404) through December 2009. Table 1, Panel A, summarizes the initial sample composition, which includes 2,219 observations with MW and 22,587 observations without MW.

We apply four screens to arrive at the final sample. First, we eliminate duplicate observations to ensure that each firm has at most only one observation included for any given year (i.e., in cases of restatements we take the last filing). Second, we eliminate observations associated with firms that report MW in multiple non-consecutive years because such an approach allows us to distinguish firms that report MW in multiple consecutive years from firms that report MW in a single year (i.e., firms reporting MW in multiple non-consecutive years fall somewhere between these two extremes).[4] Third, similar to OSR, we eliminate observations associated with firms that report MW in their Section 302 reports and subsequently do not report MW in their Section 404 reports. Finally, we eliminate observations missing the data required to calculate the control variables or the data required to calculate CE. The final sample is composed of 16,946 observations, which includes 1,140 observations with MW and 15,806 observations without MW (the control sample).[5] However, the number of observations used within each analysis varies depending on the CE measure.

Dependent Variable

As discussed in Section II, an increased CE is a potential result of MW. Thus, the dependent variable in the current study is *cost of equity* (*CE*). For comparability with previous studies (i.e., OSR and ACKL), we calculate *CE* using five established methodologies that are discussed and developed by Claus and Thomas (2001), Gebhardt et al. (2001), Gode and Mohanram (2003), Easton (2004), and Hail and Leuz (2006). We refer to these measures as CE_{CT}, CE_{GLS}, CE_{GM}, CE_{EAST}, and CE_{HL}, respectively. We use multiple measures of CE to avoid spurious results that

---

[3] Partial remediation is determined based on the number of MW reported. If the number of MW reported decreases as the firm continues to report MW in multiple consecutive years, then the firm is classified as a firm that partially remediates its MW.

[4] In response to a suggestion by one of the reviewers, all analyses are also performed with multiple non-consecutive MW firms included. The results do not differ significantly from those where the firms are eliminated. These results are available upon request.

[5] Of the 1,140 observations comprising the final sample, 805, or 70.6 percent, occur prior to 2007. In 2007, the SEC, and subsequently the PCAOB, redefined MW, moving from the definition of "a significant deficiency, or combination of significant deficiencies, that results in *more than a remote likelihood* that a material misstatement of the annual or interim financial statements will not be prevented or detected" (PCAOB 2004; emphasis added) to the definition, "a deficiency, or a combination of deficiencies, in internal control over financial reporting, such that there is a *reasonable possibility* that a material misstatement of the company's annual or interim financial statements will not be prevented or detected on a timely basis" (PCAOB 2007; emphasis in the original). Since the current study spans periods of time in which both definitions were used, we note that the change in definition may be one reason behind the decline in firms that report MW after the change in definitions took effect.

TABLE 1

Sample Selection and Categorization of Firms with Material Weaknesses (MW)

Panel A: Sample Selection[a]

MW Sample (Observations with MW)	
Total number of audit reports with MW for fiscal years 2004–2009	2,219
Eliminate duplicate observations due to financial restatements	(103)
Eliminate observations arising from reporting MW in non-consecutive years	(197)
Eliminate observations due to data restrictions imposed by the current study	(779)
Total number of material weakness observations identified for use in the current study	1,140
Control Sample (Observations without MW)	
Total number of audit reports without MW for fiscal years 2004–2009	22,587
Eliminate duplicate observations due to financial restatements	(317)
Eliminate observations associated with firms reporting MW in SOX Section 302 reports and subsequently reporting clean SOX Section 404 reports	(258)
Eliminate observations arising from reporting MW in non-consecutive years	(234)
Eliminate firm years due to data restrictions imposed by the current study	(5,972)
Total number of control observations identified for use in the current study	15,806
Total Sample	16,946

Panel B: Categorization of MW (Observations Associated with Firms Reporting Weaknesses)[b]

	MW Obs.	% of MW Obs.	% of Total Obs.
Single year	828	72.63%	4.89%
Two consecutive years	212	18.60%	1.25%
Three consecutive years	71	6.23%	0.42%
Four or more consecutive years[c]	29	2.54%	0.17%
Total Material Weakness Observations	1,140	100.00%	6.73%

[a] Panel A defines the steps employed to arrive at the final MW and control samples for firms that filed Section 404 reports during fiscal years 2004 through 2009.

[b] Panel B categorizes firms based on the number of consecutive years in which a firm reports MW. For example, if a firm reported MW in the previous two years (observations) and the current year, then the reported MW for the firm in the current year would classify the observation as a three-consecutive-years observation. This firm's observation from the previous year would be classified as two-consecutive-years observation and so on.

[c] As discussed in the text, a limited number of firms had MW in five and six consecutive years. Given the limited number of observations available in the final sample, MW beyond four years were not considered as separate categories.

could arise if any *CE* measure attributes are related to the variables of interest. Although we use all five measures to perform the analyses, only the average measure (i.e., the CE_{HL} measure) is reported in the tabulated results because of the high level of correlation among the measures and because we obtain similar results with each of the five measures.[6] The details of the five estimates of CE are described in Appendix A.

---

[6] The results of analyses using all five measures are available upon request.

Following previous studies (i.e., OSR and ACKL), we calculate the measures of *CE* as of the end of June for each year of data availability (2004–2009). Each CE measure has specific data requirements. For example, each observation must have one- and two-year-ahead EPS forecasts (*FEPS1* and *FEPS2*) and either a long-term growth forecast (*LG*) or three-, four-, and five-year-ahead earnings forecasts (*FEPS3*, *FEPS4*, and *FEPS5*). Additionally CE_{EAST} requires $FEPS1 > 0$ and $FEPS2 \geq FEPS1$. While CE_{GM} has the same restrictions as CE_{EAST}, it additionally requires $FEPS1 \geq 0$ *and* $FEPS2 \geq 0$. Finally, CE_{CT} and CT_{GLS} require us to use only observations that have positive book values of equity.

Independent Variables

H2 and H3 predict that firms that report MW in multiple consecutive years will experience a larger negative impact on CE than will firms that report MW in only a single year. Accordingly, the key independent variables in the current study are the number of consecutive years (i.e., one, two, three, and four or more) in which firms report MW. The independent variables are specified as four indicator variables. The first indicator variable, *MW1*, is set equal to 1 for observations of MW associated with firms that have not reported MW previously (0 otherwise). The indicator variables for observations that represent MW reported in two, three, and four or more consecutive years are *MW2*, *MW3*, and *MW4*, respectively. More specifically, we assign the value 1 to one, and only one, of these variables for each observation of MW dependent on whether the MW reported within the observation represent consecutive MW occurring in two, three, or more years.[7]

For example, if a firm reported MW in the previous two years and the current year, then the MW reported in the current year would classify the observation as having MW in three consecutive years (*MW3*). Thus, the firm would be assigned a 1 to the *MW3* indicator variable and 0 to the *MW1*, *MW2*, and *MW4* indicator variables in the current year's observation. This firm's prior year observation would be assigned a 1 to the *MW2* indicator variable and 0 to the *MW1*, *MW3*, and *MW4* indicator variables, and so on. Within our control sample (i.e., firms reporting zero MW), each observation without MW is assigned a value of 0 to all indicator variables (i.e., *MW1*, *MW2*, *MW3*, and *MW4*). Although the inclusion of observations through fiscal year 2009 allows for the possibility of *MW5* and *MW6* variables, due to the limited number of observations that fall within these categories (six observations, after data restrictions have been applied), we include these observations in the *MW4* variable category in all analyses.

As shown in Table 1, Panel B, the final MW sample is composed of 828 *MW1* observations, 212 *MW2* observations, 71 *MW3* observations, and 29 *MW4* observations. As noted in the table, of the 1,140 observations in the sample with MW, only 1.3, 0.4, and 0.2 percent of the total observations report MW in two, three, and four or more consecutive years, respectively. These percentages are in contrast to the 4.9 percent of the total observations associated with reporting MW for the first time. In other words, firms seem to recognize that investors expect remediation of MW, and most firms in the current study respond accordingly. However, of the 4.9 percent of firms that report MW within a single year, 26.5 percent (i.e., 1.3 percent divided by 4.9 percent) of these firms continue to report MW in a second year and 8.2 and 4.1 percent continue to report MW in three and four or more years, respectively. Arguably, 26.5, 8.2, and 4.1 percent represent a significant number of firms that do not fully remediate MW in a timely manner.

Based on prior research, we include six control variables. The first control variable is *firm size*, measured as the logarithm of each firm's market capitalization (*MKT_CAP*). As firm size increases,

---

[7] Since 2004 was the first year that firms were required to report in compliance with Section 404, the only possible observations of MW during this period would be *MW1*. Likewise, since 2005 was the second year that firms were required to report in compliance with Section 404, the only possible observations of MW during 2005 would be *MW1* and *MW2*, and so on.

CE will likely decrease, as the firm capitalizes on efficiencies associated with size (OSR). The second control variable is *firm age*, measured as the logarithm of the number of years the firm has existed within the CRSP database (*AGE_FIRM*). As firm age increases, the firm is likely to be in a better position to generate financial support through internal or external methods, resulting in a lower CE (OSR).

A firm's *financial stability* is the third control variable. To proxy for stability, we compute the sum of earnings before extraordinary items for the past two years (Doyle et al. 2007). If the sum is less than 0, then the firm is assigned an indicator variable (*LOSS*) of 1, and 0 otherwise. This variable is included to account for the expectation that firms experiencing losses over the past two years will likely have a higher CE than firms that portray a more positive financial track record (OSR). *Firm complexity* is the fourth control variable. As a firm becomes more complex, we expect complexity to affect the CE (OSR). To measure firm complexity, an indicator variable is set equal to 1 if the firm reported a foreign currency translation adjustment (*FCR*), and 0 otherwise. The fifth control variable is associated with the existence of fluctuations in a firm's sales activities. This variable, *firm fluctuation*, exhibits itself through extreme sales growth (*SL_GR*). To measure extreme sales growth, we calculate year-by-year sales growth for years *t*–2 through *t* (where *t* is the current year) and rank each observation by decile, dependent on its respective average sales growth over the previous three years (ACKL). This variable captures the possibility that a rapidly changing environment could lead to a higher CE due to risks associated with fluctuating sales growth.

The sixth control variable is *predicted analyst forecast error*. Prior CE studies point to optimistic bias in long-term analyst forecasts as a potential source of error in the measurement of CE (Claus and Thomas 2001; Gode and Mohanram 2010). Gode and Mohanram (2010) find that controlling for analyst forecast error improves the relation between CE and realized returns. Whereas OSR find initial evidence that suggests a difference in CE exists between firms reporting MW and firms not reporting MW, this evidence dissipates after they control for firm characteristics and predicted analyst forecast error. Given that the current study already controls for firm characteristics similar to those employed in OSR, we include a predicted analyst forecast error control variable to account for potential analyst forecast bias. To calculate predicted analyst forecast error (*AVGPRED_ER*), we utilize the measurement developed by Hughes et al. (2008), as detailed in Appendix A.

Model Formulation

The current study empirically examines the effect of MW reported in multiple consecutive years upon CE through ordinary least squares (OLS) models that combine the MW indicator variables with control variables. Equation (1) tests whether reported MW result in a higher CE (H1). Additionally, the MW indicator variables within Equation (1) establish whether a negative CE impact is associated with reporting MW in multiple consecutive years (H2 and H3). All variables included in the model below are defined in Appendix B:

$$\begin{aligned} CE_i = {} & \beta_0 + \beta_1{*}MW1_i + \beta_2{*}MW2_i + \beta_3{*}MW3_i + \beta_4{*}MW4_i + \beta_5{*}MKT\_CAP_i \\ & + \beta_6{*}AGE\_FIRM_i + \beta_7{*}LOSS_i + \beta_8{*}SL\_GR_i + \beta_9{*}FCR_i + \beta_{10}{*}AVGPRED\_ER_i + \varepsilon_i. \end{aligned} \tag{1}$$

The current study also considers a modified version of Equation (1) that includes a variable for the number of MW (*NW*). This modified model is shown as Equation (2) below. In Equation (2), *NW* is measured as the number of MW reported under Section 404. With the combination of the *NW* variable and the number of consecutive years in which a firm reports MW (*MW1*, *MW2*, *MW3*, and *MW4*), Equation (2) tests whether *NW* has an incremental impact on CE (H4):

$$CE_i = \beta_0 + \beta_1 * MW1_i + \beta_2 * MW2_i + \beta_3 * MW3_i + \beta_4 * MW4_i + \beta_5 * NW_i + \beta_6 * MKT\_CAP_i + \beta_7 * AGE\_FIRM_i + \beta_8 * LOSS_i + \beta_9 * SL\_GR_i + \beta_{10} * FCR_i + \beta_{11} * AVGPRED\_ER_i + \varepsilon_i. \tag{2}$$

All regression analyses use cluster-robust standard errors to avoid overstating t-statistics due to multiple observations of the same firm (different fiscal years) within the dataset (Petersen 2009; Gow et al. 2010). The current study uses panel data and, as such, we control for potential MW reporting time trends by including time fixed-effects in the regression analyses. Additionally, we control for industry fixed-effects.[8]

IV. RESULTS

Univariate Analyses

Table 2 reports descriptive statistics for the dependent and independent variables. Table 2 also displays the test results for both a two-group mean comparison test and a Wilcoxon rank-sum test.[9] Table 2, Panel A, reports and compares the variables' mean and median values for the control sample with the same values for the MW sample. The results from the two-group mean comparison test and the Wilcoxon rank-sum test indicate that observations with MW tend to have a significantly higher CE than observations without MW, which supports H1. In line with prior research results (Doyle et al. 2007; Ashbaugh-Skaife et al. 2007), the results in Table 2, Panel A, also indicate that firms with MW tend to be smaller, younger, and report losses more frequently than the firms in the control sample. Additionally, the results indicate that firms reporting MW have a significantly higher predicted analyst forecast error (*AVGPRED_ER*), highlighting the need to include *AVGPRED_ER* within the analysis to control for analyst forecast error.

Differences between the characteristics of observations within each of the MW categories (*MW1*, *MW2*, *MW3*, and *MW4*) are reported in Table 2, Panels B, C, and D. Panel B displays the results of a comparison between the *MW1* and *MW2* observations. These results indicate that *CE* is significantly higher for *MW2* observations than for *MW1* observations. Additionally, the *MW2* observations are associated with a higher percentage of foreign currency translation adjustments (*FCR*), have a significantly higher predicted analyst forecast error (*AVGPRED_ER*), and report a significantly higher number of MW (*NW*). Although most of the variable values are higher for *MW3* observations than for *MW2* observations, Panel C shows no significant differences between the *MW2* and *MW3* observation variables. However, Panel D reveals that *CE* and *NW* are significantly lower for *MW4* observations than for *MW3* observations.

The above results provide weak preliminary support for H2 and H3. Even though the difference between *CE* for *MW2* and *MW3* observations is not statistically significant, the results indicate that firms that report MW in multiple consecutive years have a higher *CE* (12.8, 13.2, and 11.2 percent as compared to 11.1 percent for *MW2*, *MW3*, *MW4*, and *MW1*, respectively). However, the statistics indicate that *MW4* observations have a lower *CE* than *MW3* observations. Although this latter result appears to conflict with H2 and H3, the descriptive statistics reveal that the average number of MW reported by *MW4* observations is lower than the number of MW reported by *MW2* and *MW3* observations (see Table 2, Panel D). We address this issue in the "Multivariate Analyses" section below. In that section, we first analyze the data utilizing a restricted sample that excludes

---

[8] We categorize industries according to the Fama-French 48 industry classification (Fama and French 1997).

[9] The two-group mean comparison test examines whether significant differences exist between the means of two groups. The Wilcoxon rank-sum test examines whether significant differences exist between the medians of two groups.

*, **, *** Statistical significance at the 0.10, 0.05, and 0.01 levels, respectively, using two-tailed tests.

[a] This table presents descriptive statistics for the current study's dependent and independent variables. Means are compared using a two-group mean comparison test (t-test) and the t-values are displayed in parentheses below the mean values. Medians are compared using a Wilcoxon rank-sum test and the z-values are displayed in parentheses below the median values. All variables are defined in Appendices A and B, unless noted otherwise. *MKT_CAP* is reported in thousands of dollars and *AGE_FIRM* is reported in years.

firms that are partially remediating their MW during the years in which they are reporting MW in multiple consecutive years.[10] We then analyze the data using the full sample identified in Table 1.

Table 3 presents the average number of MW reported by a given firm, as well as the number of firms, within each category of MW. These data indicate that, on average, the number of MW reported by a given firm declines monotonically as firms continue to report MW in multiple consecutive years. However, the average number of MW reported within the *MW1* observations increases as the number of multiple consecutive years also increases (see Table 3). More specifically, the average number of MW reported ranges from an average of 1.78 MW reported in the first year for firms reporting MW in a single year to 4.64 MW reported in the first year for firms reporting MW in four or more consecutive years. Overall, the results from Table 3 provide descriptive evidence that partial remediation is occurring. In addition as shown in Table 3, note b, the percentage of firms that are partially remediating their MW is also progressively increasing as we move from firms with *MW2* to those with *MW3* to those with *MW4* (i.e., the percentages are 14.62, 32.39, and 48.28 percent, respectively).

Multivariate Analyses

Table 4 presents OLS regression results for Equations (1) and (2). These results indicate that firm size (*MKT_CAP*), firm age (*AGE_FIRM*), firm financial stability (*LOSS*), firm complexity (*FCR*), and predicted analyst forecast error (*AVGPRED_ER*) are significantly associated with a firm's CE. These outcomes are consistent with the findings of OSR and ACKL.

As indicated in Section II, H2 and H3 do not consider the case where a firm may only partially remediate its MW. One way for a firm to signal partial remediation is through a decline in the number of MW reported in multiple consecutive years. The univariate analyses above (Table 3) indicate that firms are partially remediating and doing so at a progressively increasing rate (i.e., the more consecutive years in which a firm reports MW the more likely that a firm will participate in partial remediation).

Since partial remediation is occurring, and at a progressively increasing rate, we eliminate firms that partially remediate MW from our sample to ensure that we are able to capture the MW and CE relation (i.e., to test H2 and H3 independent of H4). With this restricted sample, we run an OLS regression using Equation (1). The results of this analysis are included in Table 4 as column (1). The results show that the indicator variables, which classify firms into categories by the number of multiple consecutive years of reporting MW, are significant for the *MW2*, *MW3*, and *MW4* observations. These results support H1, in cases where firms report MW in multiple consecutive years. That is, reporting MW results in a higher CE. The results indicate that CE is higher by approximately 1.0 percent when MW are reported in two consecutive years, 2.7 percent when MW are reported in three consecutive years, and 3.4 percent when MW are reported in four or more consecutive years. The significant *MW2*, *MW3*, and *MW4* coefficients are larger than the MW1 coefficient, and the MW4 coefficient is significantly larger than the MW3 coefficient, which is significantly larger than the MW2 coefficient. These latter results support H2 and H3.

The OLS regression results for Equation (1) (Table 4, column (1)) also indicate that if a firm reports MW for the first time, then CE is not significantly higher. This insignificant *MW1* coefficient is similar to the findings of OSR and is examined in more detail in the "Reconciling Results of Prior Research and the Current Study" section below. Nevertheless, evidence from the current study

---

[10] All univariate analyses were also run using a restricted sample (i.e., eliminating partially remediating firms). Once these firms are eliminated, our results indicate that the CE increases progressively as the number of consecutive years a firm reported MW increases. Additionally, the number of MW reported increases as the number of multiple consecutive years increases. These results are available from the authors upon request.

TABLE 3

Average Number of Material Weaknesses (MW) Reported and Number of Firms within Each Multiple Consecutive Year Category[a]

Panel A: Average # of MW Reported in Only One Year, and # of Firms

	Average # MW Reported	# of Firms[b]	Std. Dev.
MW1	1.783	624	1.734

Panel B: Average # of MW Reported in Two Consecutive Years, and # of Firms

	Average # MW Reported	# of Firms[b]	Std. Dev.
MW1	2.898	137	2.568
MW2	2.268	142	1.875

Panel C: Average # of MW Reported in Three Consecutive Years, and # of Firms

	Average # MW Reported	# of Firms[b]	Std. Dev.
MW1	4.439	41	4.348
MW2	3.500	44	3.331
MW3	3.000	47	3.593

Panel D: Average # of MW Reported in Four or More Consecutive Years, and # of Firms

	Average # MW Reported	# of Firms[b]	Std. Dev.
MW1	4.640	26	3.239
MW2	3.615	26	3.336
MW3	3.500	24	2.085
MW4	2.000	29	1.336

---

[a] Panels A, B, C, and D report the average number of MW that are attributed to firms that report MW in one, two, three, or four consecutive years, respectively.

[b] Although one would expect the number of firms to remain consistent across time, the use of I/B/E/S data to arrive at the CE estimates precludes this occurrence. However, the number of observations remains consistent with the previously defined samples used in both Tables 1 and 2. The total number of *MW1* observations is equal to 828, the total number of *MW2* observations is equal to 212, the total number of *MW3* observations is equal to 71, and the total number of *MW4* observations is equal to 29. Of the 29 firms that report *MW4*, 14 out of the 29 (i.e., 48.28 percent) firms had partially remediated their MW. For *MW3*, 23 out of 71 (32.39 percent) firms had partially remediated their MW. For *MW2*, 31 out of the 212 (14.62 percent) firms had partially remediated their MW.

suggests that if a firm does not remediate MW after the first year of reporting, then the firm will experience a higher CE as the firm continues to report MW.

To assess the impact of partial remediation (H4), we begin by running an OLS regression of Equation (1) using the full sample of firms. These results are listed in Table 4, column (2) and show that the indicator variables, which classify firms into categories by the number of multiple consecutive years of reporting MW, are significant for the *MW2* and *MW3* observations. The results indicate that CE is higher by approximately 1.0 percent when MW are reported in two consecutive

*, **, *** Statistical significance at the 0.10, 0.05, and 0.01 levels, respectively, using two-tailed tests.

[a] The column (1) analysis contains fewer observations because firm observations are removed if the firm partially remediated MW (reduced the number of MW reported in multiple consecutive years).

Columns (1) and (2) report results for the following OLS regression:

$$CE_i = \beta_0 + \beta_1{*}MW1_i + \beta_2{*}MW2_i + \beta_3{*}MW3_i + \beta_4{*}MW4_i + \beta_5{*}MKT\_CAP_i + \beta_6{*}AGE\_FIRM_i + \beta_7{*}LOSS_i + \beta_8{*}SL\_GR_i + \beta_9{*}FCR_i + \beta_{10}{*}AVGPRED\_ER_i + \varepsilon_i. \tag{1}$$

Column (3) reports results for the following OLS regression:

$$CE_i = \beta_0 + \beta_1{*}MW1_i + \beta_2{*}MW2_i + \beta_3{*}MW3_i + \beta_4{*}MW4_i + \beta_5{*}NW_i + \beta_6{*}MKT\_CAP_i + \beta_7{*}AGE\_FIRM_i + \beta_8{*}LOSS_i + \beta_9{*}SL\_GR_i + \beta_{10}{*}FCR_i + \beta_{11}{*}AVGPRED\_ER_i + \varepsilon_i. \tag{2}$$

Robust standard errors are listed in parentheses. All variables are defined in Appendices A and B.

years and higher by 1.8 percent when MW are reported in three consecutive years. The significant *MW2* and *MW3* coefficients are larger than the *MW1* coefficient and the *MW3* coefficient is significantly larger than the *MW2* coefficient. In comparing the figures in column (1) with those in column (2), it is clear that partial remediation has a positive impact on CE (i.e., reduces CE) for *MW3* and *MW4*. In fact, due to the large percentage of firms that partially remediate MW in the *MW4* case (i.e., 48 percent), the sign on *MW4* actually reverses (although it is not statistically significant). For *MW3*, 32.39 percent of the firms partially remediate their MW and this also has a positive impact (i.e., reduction) on the CE of the firms, although this impact is not enough to reverse the sign. In the case of *MW2*, only 14.62 percent of the firms partially remediate, with no statistical impact on the analysis. These results support H4.

We also examine the impact of partial remediation through Equation (2). Equation (2) allows us to directly examine the impact of the number of MW on CE, using all observations within the sample. The results from Table 4, column (3), indicate that the number of MW is positively and significantly related to CE. This evidence provides additional support for H4 that a reduction in the number of MW (i.e., partial remediation) results in a lower CE for firms that report MW in multiple consecutive years. More specifically, firms experience a 0.1 percent decrease in CE for each of the MW that are remediated. The two analyses provided in columns (2) and (3) indicate that partial remediation, rather than the presence or absence of MW, is a factor that leads to a lower CE.[11]

Overall, the results of Table 4 provide evidence in support of all four of our hypotheses. To summarize, the results indicate that reporting MW leads to a higher CE. Moreover, absent partial remediation, reporting MW in multiple consecutive years results in a higher CE than that obtained if a firm reports MW in a single year and CE is progressively higher as firms continue to report MW in consecutive years. Additionally, the evidence suggests that firms that report MW in multiple consecutive years and partially remediate their MW over the multiple consecutive years experience a lower CE.

Reconciling Results of Prior Research and the Current Study

Based on data filed with the SEC from November 2004 through January 2006, and after controlling for key firm characteristics, OSR (2007, 1256) conclude that SOX Section 404 MW "do not appear to be directly associated with cost of equity." They also conclude that remediation of MW does not lower CE. In contrast, based on reports filed with the SEC under SOX Sections 302 and 404 during the time period of November 2003 through September 2005, ACKL find that MW are associated with a lower CE. ACKL also find, based on intertemporal change analyses, that remediation of MW is associated with a decrease in CE. As we show in the subsequent analyses, these differing results appear to be driven by the fact that ACKL include Section 302 MW, as well as Section 404 MW, whereas OSR only consider Section 404 MW. Results from the current study indicate that, while CE is not higher during the first year of MW reporting (consistent with OSR), there is a progressively significant and negative impact on CE when a firm reports MW in two, three, and four consecutive years (consistent with ACKL), as displayed in Table 4, column (1). The current study also finds that remediation of Section 404 MW is associated with a lower CE (consistent with ACKL), especially when such remediation occurs after reporting MW in multiple consecutive years.

ACKL note that "[o]ne potential explanation for the 'no association' result in the OSR study is due to their research design choice to 'look ahead' to a future SOX 404 audit opinion to determine their coding of firms' internal control status" (ACKL 2009, 37). ACKL perform two steps to reconcile their results with OSR. First, they replicate the OSR approach using the ACKL Section 404 MW data. Within this step, firms that report Section 302 MW and subsequently do not report Section 404 MW are coded as firms that *do not* report Section 404 MW. The OLS regression results of this first step closely resemble those of OSR. As a second step, ACKL recode firms that report Section 302 MW and do not report Section 404 MW as firms that *do* report Section 404 MW, resulting in OLS regression results that are similar to those obtained within the first part of the ACKL study. ACKL follow most of the procedures utilized by OSR. However, the OSR study does not suffer from this "look-ahead bias" because it eliminates observations that report Section 302 MW and subsequently report no Section 404 MW. Thus, the replication performed by ACKL does not exactly follow OSR.

---

[11] As noted previously, earlier studies did not fully examine this issue because they did not include more than two years of data. The constrained samples were due, in large part, to the time period in which those studies were completed.

In light of the similar focus of the current study to the OSR and ACKL studies, this section attempts to reconcile the differences between OSR and ACKL using currently available data, as well as reconcile the results from the current study to the results from these two prior studies. Our reconciliation follows a three-step procedure.[12] As a first step, we replicate the OSR and ACKL studies within their respective time periods. The ACKL replication includes both Section 302 MW and Section 404 MW. On the other hand, only Section 404 MW are used in the OSR replication. The replications follow the steps employed within the original two studies. In untabulated findings, the replications of these studies produce results similar to those noted in the preceding paragraph. Since the main difference between OSR and ACKL is that ACKL include MW reported under both Section 302 and Section 404, the current study also replicates ACKL after removing Section 302 MW from the sample. This additional procedure examines whether Section 302 MW are the driving force behind the differing results between the OSR and ACKL studies. After removing Section 302 MW from the current study's replication of ACKL, these results reconcile to the current study's replication of OSR.[13]

It is important to recall that the OSR and ACKL studies were conducted several years prior to the current study. More specifically, OSR base their data set on annual SEC filings reported no later than January 2006 and ACKL base their data set on annual and quarterly SEC filings reported no later than September 2005. In contrast, the current study includes Section 404 MW from annual SEC filings reported from 2004 through 2009. Given the availability of additional data, we use the same data as used in Table 4, column (1) (i.e., the sample that excludes firms that partially remediate their MW), and as part of the second step in the reconciliation process, we separate the Section 404 MW into two distinct time periods, with the earlier period paralleling the OSR time frame. The later time period starts at the point that the earlier one ends. More specifically, we split MW into two subsamples dependent upon the time period in which they occur: (1) November 2004 through January 2006, and (2) February 2006 through December 2009. Given that the results from the current study indicate the *MW1* coefficient is insignificant, as a variation on the above data split, we also split the set of observations with MW into the following two different subsamples: (a) *MW1* observations, and (b) *MW2*, *MW3*, and *MW4* observations. After splitting the data, the second step examines the differences and similarities between the types of MW reported in the current study's subsamples and the types of MW reported in the OSR and ACKL replications. The types of MW are taken from Audit Analytics, which categorizes each MW into one of 21 different types, as listed in Table 5. The listed MW names provide a description of MW that are included in each type.

The above subsamples include the following: (1) MW derived from the OSR replication, (2) all (i.e., Section 302 and Section 404) MW derived from the replication of ACKL, (3) Section 302

---

[12] We thank one of the anonymous reviewers for suggesting that we follow the first two of these three steps.

[13] Details associated with the reconciliation results discussed in this paragraph are available from the authors upon request.

MW derived from the replication of ACKL, (4) Section 404 MW derived from the replication of ACKL, (5) Section 404 MW reported from November 2004 through January 2006 (i.e., the current study's earlier time period), (6) Section 404 MW reported from February 2006 through December 2009 (i.e., the current study's later time period), (7) *MW1* observations from the current study, and (8) *MW2*, *MW3*, and *MW4* observations from the current study.[14]

In untabulated analyses, results of two-group mean comparisons indicate that the types of MW reported within the total ACKL MW sample differ significantly from the types of MW reported within the OSR MW sample. To provide a clearer picture of the ACKL MW sample composition, we separate the total ACKL sample into Section 302 MW and Section 404 MW. The ACKL Section 404 MW type composition is similar to the OSR MW type composition. However, the ACKL Section 302 MW type composition differs significantly from the OSR MW type composition. More specifically, these results suggest that entity-level types of MW (i.e., information technology, software and security issues, ethical or compliance issues with personnel, etc.) are more prevalent within the ACKL Section 302 MW sample.[15,16]

A comparison between the MW type composition of the OSR MW sample and the current study's earlier time period 404 MW sample reveals that the types of MW reported within the earlier time period closely resemble those reported within the OSR MW sample. The observations from the current study's later time period 404 MW sample differ significantly from the OSR MW sample and the observations from the current study's earlier time period. We then compare the types of MW reported in the ACKL Section 302 MW sample and the types of MW reported in the current study's later time period 404 MW sample to the types of MW reported in the OSR MW sample. These latter results indicate that the types of MW reported in the OSR MW sample differ significantly from the types of MW reported in the ACKL Section 302 MW sample and the current study's later time period 404 MW sample. In particular, the ACKL Section 302 MW and the current study's later time period 404 MW include a significantly higher percentage of entity-level MW than in the OSR sample. The similarities in the composition between the ACKL 302 MW sample and the current study's later time period 404 MW sample help to explain why the overall findings from the current study are consistent with the ACKL finding of a significant association between MW and CE. Table 5 displays the types of MW reported in the current study's earlier and later time periods as well as a two-group mean comparison between the types of MW from these two subsamples.

To investigate the current study's insignificant *MW1* coefficient, we examine differences in the MW composition types reported within the *MW1* observations and the *MW2*, *MW3*, and *MW4* observations (Table 6, column (4)). The results of this analysis reveal that the two groups of observations differ significantly across several types. For example, *MW1* observations have a significantly lower ($p < 0.01$) occurrence of types of MW that involve training, information technology, and journal entry control issues. As an additional analysis, Table 6 compares the *MW1* observation types (column (2)) and the *MW2*, *MW3*, and *MW4* observation types (column (3)) to the types of MW within the OSR sample (column (1)). These results indicate that the current study's *MW1* observations have a type composition similar to the OSR sample and have a significantly higher ($p < 0.01$) occurrence of MW for only three of the MW types. On the other hand, significant differences appear between the OSR sample and the current study's multiple

---

[14] The subsamples from the current study are taken from the MW sample that does not include firms that partially remediate. This sample includes 795 *MW1* observations, 181 *MW2* observation, 48 *MW3* observations, and 15 *MW4* observations.

[15] Entity-level weaknesses are weaknesses in company-level controls that encompass the control environment of the financial reporting process. Entity-level weaknesses are more difficult to remediate.

[16] Details associated with these results are available from the authors upon request.

TABLE 5

Comparison of Material Weakness (MW) Types between Firms that Report MW in Earlier and Later Time Periods[a]

TABLE 5 (continued)

*, **, *** The statistical significance between sample means is indicated at the 0.10, 0.05, and 0.01 levels, respectively.

[a] The 11/04–1/06 Observations are those observations within our sample that are reported in the same time period as the sample used by Ogneva et al. (2007), November 2004 through January 2006. The 2/06–12/09 Observations are those observations within our sample that are reported after the time period employed within the Ogneva et al. (2007) study, February 2006 through December 2009. This table compares the percentage of firms reporting specific types of MW during the earlier time period with the percentage of firms reporting specific MW during the later period. Means are compared using a two-group mean comparison test (t-test) and the t-value results are displayed in parentheses.

[b] MW Type is defined in the Audit Analytics Database. Audit Analytics categorizes each MW within one of 21 different categories.

consecutive year MW observations sample, as indicated in Table 6, column (3). In other words, the types of MW in multiple consecutive years center on policy and personnel issues (e.g., accounting documentation, policy, or procedure; ethical or compliance issues with personnel; information technology, software, security, and access issues). These entity-level MW take longer to remediate, either due to cost or difficulty in implementing change. Also, the types of MW reported in the current study's multiple consecutive year observation sample are similar to the types of MW reported within the ACKL Section 302 sample.

As a third and final step in the reconciliation process, we examine the impact of MW and remediation of MW on CE, within the current study's subsamples, through untabulated OLS regressions of Equation (1). We also include the control firms in these regressions. The results that utilize the current study's earlier and later time period samples indicate that the *MW1* coefficient is insignificant for the earlier time period sample. Alternatively, the *MW1*, *MW2*, *MW3*, and *MW4* coefficients are each positive and significant for the later time period sample. The regression results from the *MW1* observation sample indicate that *MW1* observations taken as a complete group are not significantly related to a higher CE. However, the regression results from the multiple consecutive year MW observations group indicate that the *MW2*, *MW3*, and *MW4* coefficients are significant and positive. Thus, the regression results indicate that the types of MW that are similar to those reported within the OSR study are not significantly associated with a higher CE. However, the types of 404 MW that are similar to those reported within the ACKL study (i.e., the 302 MW) are significantly associated with a higher CE.[17]

In sum, the current study helps to reconcile the differing results in the OSR and ACKL studies, in terms of the types of MW reported under Sections 302 and 404 and the different time periods in which the MW are reported. This reconciliation shows that MW, in general, do indeed lead to a higher CE. In addition, remediation of these MW appears to result in a lower CE. Both of these findings support the original findings of the ACKL study.

V. ROBUSTNESS CHECKS

The robustness results discussed below are based on firms that do not partially remediate their MW when they report MW in multiple consecutive years (i.e., the MW sample from Table 4, column (1)). Although not discussed below, in untabulated results, we use the full MW sample and find results similar to those obtained in Table 4, column (2).[18]

---

[17] The results of these regressions are available from the authors upon request.

[18] The results that use the full MW sample are available from the authors upon request.

TABLE 6 (continued)

*, **, *** The statistical significance between sample means is indicated at the 0.10, 0.05, and 0.01 levels, respectively.

[a] The OSR Sample is composed of observations that were collected to perform a replication of the Ogneva et al. (2007) study. The *MW1* observations are observations from the current study that are associated with firms that have reported MW for the first time. The *MW2*, *MW3*, and *MW4* observations are observations from the current study that are associated with firms that are reporting MW for at least a second time. This table compares the percentage of firms reporting specific types of MW for the first time and for at least a second time (columns (2) and (3)) with the types of MW reported within the Ogneva et al. (2007) study. Additionally, this table compares the difference between the types of MW observed in firms that are reporting MW for the first time compared to firms that are reporting MW for at least a second time (column (4)). Means are compared using a two-group mean comparison test (t-test) and t-values are displayed in parentheses.

[b] MW Type is defined in the Audit Analytics Database. Audit Analytics categorizes each MW within one of 21 different categories.

Control Variables

Prior research uses different metrics for *firm financial stability*, *firm complexity*, *firm fluctuation*, and *predicted analyst forecast error* (OSR; ACKL). To confirm that the results are robust to different specifications for each of these variables, we recomputed the analyses after substituting different proxies for each of these control variables in Equation (1).[19] We check the robustness of the firm financial stability measure using two additional metrics in lieu of the two-year loss measure: (1) the Altman Z-score decile ranking (Doyle et al. 2007), developed by Altman (1968), and (2) leverage (Ashbaugh-Skaife et al. 2007). With respect to firm complexity, we substitute the number of business segments (Doyle et al. 2007) in place of the foreign currency translation metric. Additionally, in lieu of extreme sales growth as a proxy for firm fluctuations, we repeat the analyses with a measure that represents restructuring (Doyle et al. 2007). The results remain robust to each of these alternative specifications.

The prior published CE literature examines the impact of analyst forecast bias on CE estimates and uses a predicted analyst forecast error measure as a control variable (Dhaliwal et al. 2005; OSR; Hughes et al. 2008). As such, the current study tests whether the regression results are also robust to two alternative predicted analyst forecast error estimates that are developed within the OSR and Gode and Mohanram (2010) studies. OSR employ a variation of the Hughes et al. (2008) measure as their proxy for analyst forecast error and include this measure as a control variable. Substituting the OSR measure into the previous analyses does not significantly affect the main results. As an alternative to the control variable approach, Gode and Mohanram (2010) remove the predicted analyst forecast error from the earnings estimates prior to calculating CE. Accordingly, we examine whether there is a difference in the results when the error estimates are removed directly from the analysts' forecasts. Results (untabulated) remain robust to using the CE_{EAST} measure of CE, which is the CE measure used by both ACKL and OSR. Appendix B describes the calculations for each of the above variables.[20]

Change in Cost of Equity

The main analyses measure the *CE* variable (i.e., the dependent variable) in terms of the absolute level of CE. However, to provide additional robustness to the results, we recomputed Equation (1) with the *CE* variable measured in terms of changes in CE. Given the possibility that other events and firm factors could concurrently affect CE, the results using the different measure of CE provide additional support for the main results concerning the positive relation between MW and CE, as well as the positive relation between reporting MW in multiple consecutive years and CE. However, because we use I/B/E/S data to calculate *CE*, the number of available observations is reduced when we measure CE in terms of its change.[21] We calculate the change in CE for each year *t* observation as the difference between CE as of the end of June, year *t*+1 and CE as of the end of June, year *t*. The June date is used because the annual reports, and thus Section 404 MW, for most firms are not filed with the SEC until after December and before the end of June. For example, we measure the change in CE for 2004 as the difference between CE at the end of June of 2005 and CE at the end of June of 2004. Accordingly, for the overwhelming majority of firms within the sample,[22] the change in CE is post-disclosure CE (but prior to the next disclosure) minus pre-disclosure CE. This method of measuring the change in CE is similar to that used by ACKL.

---

[19] To avoid issues associated with multicollinearity, multiple metrics are not assigned to each independent control variable in the main analyses.

[20] The details associated with these results are available from the authors upon request.

Based on this change measure of CE, we recompute all prior analyses to assess whether the results remain robust to this new measure of the dependent variable. The findings show that the previous results are robust, and even stronger, when we measure CE as a change variable. More specifically, as shown in Table 7, the results indicate that MW are associated with an increase in CE that intensifies as a firm continues to report MW in consecutive years.

Difference-in-Differences

It may be possible that the differences in CE between firms that completely remediate MW and those that do not remediate MW are driven by omitted and unobserved differences over time. Another approach to mitigate this concern, aside from regression analyses that measure the change in CE as the dependent variable, is the difference-in-differences method. Accordingly, we examine the difference in the average CE prior to remediation and following remediation for both sets of firms (i.e., the set of firms that completely remediate and the set of firms that do not remediate). A significantly larger decrease in CE for firms that completely remediate relative to firms that do not remediate would provide additional evidence of the benefits of remediation.

To conduct the difference-in-differences analyses, we divide the sample into two-year time periods (2004–2005, 2005–2006, etc.) and measure the difference in CE for firms that completely remediate versus firms that do not remediate over each two-year period using all five *CE* measures that are described in Appendix A. Table 8 reports the results of the analyses using the CE_{HL} measure (i.e., the average measure). Limitations in the size of the control (no remediation) and treatment (remediation) samples prevent use of the 2008–2009 period.[23] The difference-in-differences results obtained using the average *CE* measure indicate a strong association between complete remediation and a lower CE. More specifically, Table 8 shows that the difference in CE for firms that remediated (i.e., treatment firms) as compared to the firms that did not remediate (i.e., the control firms) is larger in the time period after remediation. These findings corroborate our earlier findings that remediation of MW results in a

---

[21] I/B/E/S coverage is not consistent throughout time for the firms under consideration in the current study.

[22] Eighty percent of firms in the sample have a December 31 year-end and will likely file their annual reports with the SEC between March and April of the following year. Additionally, the majority of firms within the sample (95 percent) have a year-end that ranges from June 30 to February 28. As such, the current method for calculating the change in CE takes the difference between pre-disclosure CE and post-disclosure CE.

[23] Limitations in the sample size are due to the inconsistency of available I/B/E/S estimates for the firms involved in the period under review.

TABLE 7

The Relation between Multiple Consecutive Material Weaknesses (MW) and Change in Cost of Equity (CE_{HL})[a]

CE Measure	(1) ΔCE_{HL}[b]

*, **, *** Statistical significance at the 0.10, 0.05, and 0.01 levels, respectively.

[a] The remediation sample is composed of observations that report MW in the first year examined and remediate all MW by the next year examined. The non-remediation sample is composed of firms that report MW in both years. The difference-in-difference estimator is calculated as the difference between the difference of the mean CE estimates for the remediation sample and the difference between the mean CE estimates for the non-remediation sample. CE_{HL} is defined in Appendices A and B.

Returns Analyses

As an additional robustness check, we substitute stock market returns as the dependent variable in Equation (1). Prior event studies have examined the market's reaction to MW (Beneish et al. 2008; Hammersley et al. 2008; Ashbaugh-Skaife et al. 2009). CE is theoretically the expected return required by shareholders and an indirect measure of firm performance. However, substituting actual cumulative stock market returns as the dependent variable provides additional support as to whether there is a significant association between the number of multiple consecutive years in which MW are reported and firm returns. We measure stock returns for each observation as the firm's 12-month cumulative return minus the 12-month cumulative return of a CRSP market value-weighted index. The untabulated results reveal that reporting MW results in a lower return. Additionally, and in line with the results that employ CE as the dependent variable, the severity of the decrease in returns is significantly greater as the number of multiple consecutive years increases.[25,26]

Potential Explanations for Consecutive Material Weaknesses

Firms that report MW in multiple consecutive years (i.e., firms that are not quick to remediate MW) could be doing so for several different reasons, including the following three potential explanations.[27] First, the difficulty associated with remediating certain types of MW may limit a firm's ability to fully remediate MW. Second, it may be that a firm realizes the importance of remediation but does not have the financial resources necessary to remediate. Firms falling into this second potential explanation would likely be suffering from financial distress. Third, a firm may be slow to remediate MW because the monitoring component in its internal control framework is ineffective (i.e., ineffective monitoring is only one potential explanation for the lack of remediation).[28]

Table 9 displays comparisons of the types of MW between each of the MW groups (*MW1*, *MW2*, *MW3*, and *MW4*). Firms continue to report entity-level MW—MW that take a longer period of time to remediate—in multiple consecutive years (i.e., (1) accounting personnel resources, competency, and training, and (2) information technology, software, security, and access issues). Although it is clear that certain types of MW take a longer period of time to remediate, the relation between CE and specific types of MW has not yet been examined. Equation (3) uses all observations (firms with partial remediation are included) within our sample to test whether the types of MW reported impact CE:

$$CE_{HLi} = \beta_0 + \beta_n * \sum_{i=1}^{n} MW\_Type + \alpha_n * \sum_{i=1}^{n} Control\_Variables + \varepsilon_i. \tag{3}$$

As indicated by the OLS regression results in Table 10, entity-level MW are more closely associated with a higher CE. The results from the above analysis provide evidence that it is the

---

[25] Sluggishness in revisions could cause analysts to not fully adjust their forecasts to reflect negative news (Guay et al. 2011). If the forecasts are not adjusted accordingly, then the CE measures would be biased upward at a progressive rate as firms continue to report MW consecutively, explaining the result. However, forecast sluggishness is included in the calculation of the predicted analyst forecast measure (see Appendix B). Since this variable is already accounted for within the predicted analyst forecast measure, we do not include an additional variable to account for forecast sluggishness.

[26] The details of these results are available from the authors upon request.

[27] We thank Daniel Beneish for originally suggesting the need to discuss possible explanations for firms not remediating MW.

[28] The Committee of Sponsoring Organizations of the Treadway Commission (COSO) clearly discusses the monitoring component of internal control (COSO 1992, 2009).

[a] MW Type is defined as represented through the Audit Analytics Database. Audit Analytics categorizes each MW within one of 21 different categories.

[b] Table 10 presents the following OLS regression:

$$CE_{HLi} = \beta_0 + \beta_n * \sum_{i=1}^{n} MW\_Type + \alpha_n * \sum_{i=1}^{n} Control\_Variables + \varepsilon_i. \tag{3}$$

Compared with Equation (1), this regression examines MW type instead of the number of consecutive years MW is reported. Robust standard errors are included within the parentheses. Variables are defined in Appendices A and B, unless otherwise noted.

entity-level types of MW that tend to persist for several years (e.g., ethical or compliance issues with personnel; information technology, software, and security access issues; segregations of duties/design of controls) that have a significant negative effect on CE.

As evidenced by the regression results in Tables 4, 7, and 10, a firm's financial condition (proxied by the *LOSS*[29] variable) is a significant factor that is associated with a higher CE. Furthermore, Table 2 indicates that the *LOSS* variable is significantly different between firms that report MW and firms that do not report MW (i.e., poor financial conditions are associated with a higher CE). The significant difference between observations with and without MW indicates that a higher percentage of firms that report losses are also more likely to report MW. Moreover, weak evidence reveals that the percentage of firms that report losses increases as the number of consecutive years in which MW are reported increases. These findings suggest that financial constraints are another reason why firms do not quickly remediate MW.

The dataset restricts our ability to examine whether ineffective monitoring helps to explain a firm's inability to quickly remediate MW (i.e., the third potential explanation as to why firms do not quickly remediate MW). Nevertheless, the current study does have some indirect evidence related to this issue. This indirect evidence, shown in Tables 3 and 4, is based on the decreasing number of MW reported in multiple consecutive years (i.e., partial remediation) by firms. In other words, the decreasing number of MW reported in multiple consecutive years suggests that firms are indeed monitoring MW. COSO (2009, 2) defines effective monitoring as the ability of a firm to "identify and correct internal control problems on a timely basis." Thus, firms that continue to report MW in consecutive years may have an ineffective monitoring system. However, the decreasing number of MW reported in multiple consecutive years could be attributed to both the difficulty of remediation as well as a lack of financial resources (i.e., the first two explanations noted above). The current study's data do not enable us to separate these possibilities. Thus, we are unable to draw any definitive conclusions regarding this third potential explanation as to why firms do not quickly remediate MW.

VI. CONCLUDING COMMENTS

Academicians and practitioners recognize and document the importance of good internal control to the survival of organizations. However, the empirical evidence related to firms with poor internal control was scant, at best, until the passage of SOX. Mandatory reporting of material weaknesses (MW) under SOX has resulted in the creation of large empirical databases. These databases have spawned multiple studies. A key issue addressed in this literature concerns the relation between MW and CE. The primary purpose of the current study has been to shed new light on this relation, with particular emphasis on the role of remediation of MW.

Our findings provide evidence that MW negatively impact a firm's CE. We also find evidence of the value associated with remediation of MW. Specifically, the current study shows that the market penalty imposed upon a firm's CE, in the absence of any remediation of MW, increases in relation to the number of consecutive years in which the firm reports MW. However, the results from the current study also show that the market views favorably a reduction in the number of MW reported (i.e., partial remediation). In other words, remediation is not an all-or-nothing proposition. Due to the use of a much larger and richer dataset, the current study helps to reconcile the mixed findings in earlier studies that examine the association between MW and CE. In this latter regard, the overall findings from the current study corroborate those found by Ashbaugh-Skaife et al. (2007).

---

[29] Loss is measured as the sum of earnings before extraordinary items (Compustat Data item IB) in years t and $t-1$. If this sum totals less than 0, then the firm is assigned an indicator variable of 1, and 0 otherwise.

As with nearly all empirical studies, ours has its limitations, of which two seem most notable. First, agency concerns are not considered in the current study. However, agency concerns are potentially an important issue that should be addressed in future research that examines the effects of multiple consecutive MW on organizations. Second, the current study does not consider the recent trend that some firms are following in implementing technology-based internal control monitoring systems. It would be interesting to explore the association between multiple consecutive years of MW and technology-based internal control monitoring systems. The above limitations notwithstanding, the current study provides a valuable step forward in enhancing the understanding of the way MW impact the survivability of firms.

APPENDIX A

CALCULATIONS FOR COST OF EQUITY MEASURES AND PREDICTED ANALYST FORECAST ERROR

Data definitions that are common to all measurements:

P_0 = I/B/E/S reported price of common stock as of the end of June in year *t*;

$BVPS_i$ = book value of equity per share as of year-end *t*–1;

DPS = dividends per share paid during year *t*–1;

LG = I/B/E/S reported consensus long-term growth forecast as of June in year *t*;

$FEPS_i$ = I/B/E/S reported forecasted earnings per share for year *t*+*i*. Example: *FEPS1* and *FEPS2* are the one- and two-year-ahead consensus forecasts reported in June of year *t*.

When $FEPS > 2$ is not available, we calculate consensus forecasts using LG applied to the last available forecast;

$k =$ dividend payout ratio, calculated as dividends divided by net income; and

$r_f =$ risk-free rate, set equal to ten-year Treasury note yield as of the end of June year t.

Cost of Equity Measures

Claus and Thomas (2001)

$$P_0 = BVPS_0 + \frac{ABE_1}{(1+CE_{CT})} + \frac{ABE_2}{(1+CE_{CT})^2} + \frac{ABE_3}{(1+CE_{CT})^3} + \frac{ABE_4}{(1+CE_{CT})^4} + \frac{ABE_5}{(1+CE_{CT})^5} + \frac{ABE_5(1+g)}{(CE_{CT}-g)(1+CE_{CT})^5},$$

where: $ABE_i =$ abnormal earnings ($FEPS_i - CE_{CT} * BVPS_{i-1}$). As discussed above, $FEPS_i$ is equal to the consensus forecast, if available, if not, then $FEPS_i = FEPS_{i-1} * (1+LG)$;

$BVPS_i = BVPS_{i-1} - (k * FEPS_i) + FEPS_i$; and

$g =$ growth in abnormal earnings, $r_f - 0.03$.

Gebhardt, Lee, and Swaminathan (2001)

$$P_0 = BVPS_0 + \frac{ROEF_1 - CE_{GLS}}{(1+CE_{GLS})} BVPS_0 + \frac{ROEF_2 - CE_{GLS}}{(1+CE_{GLS})^2} BVPS_1 + TV,$$

$$TV = \sum_{i=3}^{T-1} \frac{ROEF_i - CE_{GLS}}{(1+CE_{GLS})^i} BVPS_{i-1} + \frac{ROEF_T - CE_{GLS}}{(1+CE_{GLS})^{T-1}} BVPS_{T-1},$$

where:

$ROEF_i =$ forecasted return on equity for year t. For years one through three $ROEF_i$ is calculated as $FEPS_i/BVPS_i$. $ROEF_i$ is calculated as a linear extrapolation to the median industry return on equity;

$BVPS_i = BVPS_{i-1} - (k * FEPS_i) + FEPS_i$; and

$T =$ forecast horizon set equal to 12.

Gode and Mohanram (2003)

$$CE_{GM} = A + \sqrt{A^2 + \frac{FEPS1}{P_0}\left(g_2 - (\gamma - 1)\right)},$$

where:

$$A = \frac{1}{2}\left((\gamma - 1) + \frac{k*FEPS1}{P_0}\right) \text{ and } g_2 = \frac{(FEPS2 - FEPS1)}{FEPS1},$$

$\gamma = 1 - (r_f - 0.03)$.

Easton (2004)

$$CE_{EAST} = \sqrt{\frac{(FEPS2 - FEPS1)}{P_0}}.$$

Hail and Leuz (2006)

$$CE_{HL} = \frac{CE_{CT} + CE_{GLS} + CE_{GM} + CE_{EAST}}{4}.$$

Predicted Analyst Forecast Error

The metric we utilize as a proxy for analyst forecast error mirrors that modeled by Hughes et al. (2008). We calculate forecast error associated with one-year-ahead (ER_F1_i) and two-year-ahead (ER_F2_i) forecasts, for each observation, separately as follows:

$$\begin{aligned} ER\_F1_i = {} & \alpha_0 + \alpha_1 {*} FABRET_i + \alpha_2 {*} MVE_i + \alpha_3 {*} COV1_i + \alpha_4 {*} ACCRUAL_i + \alpha_5 {*} LTG_i \\ & + \alpha_6 {*} LTSG_i + \alpha_7 {*} CHG\_PPE_i + \alpha_8 {*} CHG\_OLTA_i + \alpha_9 {*} QES_i + \alpha_{10} {*} ARET_i \\ & + \alpha_{11} {*} REV1_i + \varepsilon_i; \end{aligned}$$

$$\begin{aligned} ER\_F2_i = {} & \alpha_0 + \alpha_1 {*} FABRET_i + \alpha_2 {*} MVE_i + \alpha_3 {*} COV2_i + \alpha_4 {*} ACCRUAL_i + \alpha_5 {*} LTG_i \\ & + \alpha_6 {*} LTSG_i + \alpha_7 {*} CHG\_PPE_i + \alpha_8 {*} CHG\_OLTA_i + \alpha_9 {*} QES_i + \alpha_{10} {*} ARET_i \\ & + \alpha_{11} {*} REV2_i + \varepsilon_i, \end{aligned}$$

where:

ER_F1, *ER_F2* = median consensus analyst forecast error, measured as actual I/B/E/S earnings for the fiscal year being estimated minus the median analyst estimate divided by stock price. Earnings estimates and stock price are measured as of June of year *t* (prior to submission of financial reports indicating results of the internal control audit);

FABRET = future abnormal stock returns adjusted for size. Returns are accumulated for the 13-month period following error measurement;

MVE = market value of equity, measured as the share price multiplied by the number of shares outstanding from I/B/E/S. Measured as of June of year *t*;

COV1, *COV2* = coverage by analyst for each forecast, measured as the number of analysts that issued earnings forecasts within I/B/E/S at the time of measurement;

ACCRUAL = accounting accruals measured for most recent annual earnings (*t*–1). Measured using the balance-sheet method (change in current assets minus change in cash minus change in current liabilities plus change in current portion of long-term debt minus depreciation). Accrual amount is then divided by average total assets for the previous two years;

LG = long-term EPS growth rate forecast submitted by analysts, measured at June of year *t*;

LTSG = sales growth rate over the past five years;

CHG_PPE = change within the property, plant, and equipment account over year *t*–1 divided by average total assets over the past two years;

CHG_OLTA = change within other long-term assets account over year *t*–1 divided by average total assets over the past two years;

QES = median consensus analyst forecast error for the most recent quarter divided by stock price;

ARET = annual return calculated as the stock return over the past 12 months prior to the calculation of forecast error; and

REV1, *REV2* = analyst forecast revision during the three months prior to the calculation of the forecast error divided by stock price.

The above equations are estimated separately using a pooled sample. The pooled sample is obtained by gathering all available forecast data for the five years prior to the fiscal year for which we predict the error. After estimating coefficients for the models using all available previous data, we apply these coefficients to our data to obtain predicted forecast error estimates for the one- and two-year-ahead forecasts. We then average the one- and two-year-ahead forecasts and use the resulting variable (*AVGPRED_ER*) within our analyses.

APPENDIX B
DEFINITION OF VARIABLES

Dependent Variables

CE_{CT} = Claus and Thomas (2001) as described within Appendix A;
CE_{GLS} = Gebhardt et al. (2001) as described within Appendix A;
CE_{GM} = Gode and Mohanram (2003) as described within Appendix A;
CE_{EAST} = Easton (2004) as described within Appendix A; and
CE_{HL} = average of the four measures discussed within Appendix A.

Independent Variables

MW1 = if the observation represents material weaknesses reported for the first time (no previous MW reported), then it is assigned an indicator variable of 1, 0 otherwise;
MW2 = if the observation represents material weaknesses reported in a second consecutive year, then it is assigned an indicator variable of 1, 0 otherwise;
MW3 = if the observation represents material weaknesses reported in a third consecutive year, then it is assigned an indicator variable of 1, 0 otherwise;
MW4 = if the observation represents material weaknesses reported in four or more consecutive years, then it is assigned an indicator variable of 1, 0 otherwise;
MKT_CAP = log of the share price at the end of the fiscal year multiplied by the number of common shares outstanding (log(Compustat Data item PRCF_F × Compustat Data item CSHO));
AGE_FIRM = log of the number of years the firm has been reporting within CRSP;
LOSS = sum of earnings before extraordinary items (Compustat Data item IB) in years *t* and (*t*–1). If this sum totals less than 0, then the firm is assigned an indicator variable of 1, 0 otherwise;
FCR = if the firm has a non-zero value associated with the foreign currency translation (Compustat data item FCA) item, then the observation is assigned an indicator variable of 1, 0 otherwise;
SL_GR = decile ranking of the year over year sales growth (Compustat data item SALE) for years *t*–2 through *t*; and
AVGPRED_ER = measured as the average of the predicted forecast bias measured for one- and two-year-ahead predicted forecasts as measured by Hughes et al. (2008), described in Appendix A.

Additional Independent Variables Used in Various Analyses

NW = the number of material weaknesses reported in each observation as identified by Audit Analytics;
Z_SCORE = measured as a decreasing decile ranking of the Altman (1968) Z-score;
LEV = leverage calculated as current liabilities plus long-term debt divided by total assets;

SEG = measured as the number of business segments reported in the Compustat Segments File;
$RESTRUCTURE$ = assigned an indicator variable of 1 if any of the Compustat restructuring items are different from 0, 0 otherwise;
$AVGPRED\_ER_{OSR}$ = measured using methodology of Ogneva et al. (2007); and
$AVGPRED\_ER_{GM}$ = measured using methodology of Gode and Mohanram (2010).

The Impact of Mandatory IFRS Adoption on Audit Fees: Theory and Evidence

Jeong-Bon Kim

Xiaohong Liu
The University of Hong Kong

Liu Zheng
City University of Hong Kong

ABSTRACT: This study examines the impact of International Financial Reporting Standards (IFRS) adoption on audit fees. We first build an analytical audit fee model to analyze the impact on audit fees for the change in both audit complexity and financial reporting quality brought about by IFRS adoption. We then test the model's predictions using audit fee data from European Union countries that mandated IFRS adoption in 2005. We find that mandatory IFRS adoption has led to an increase in audit fees. We also find that the IFRS-related audit fee premium increases with the increase in audit complexity brought about by IFRS adoption, and decreases with the improvement in financial reporting quality arising from IFRS adoption. Finally, we find some evidence that the IFRS-related audit fee premium is lower in countries with stronger legal regimes. Our results are robust to a variety of sensitivity checks.

Keywords: *IFRS adoption; audit fees; audit complexity; reporting quality; legal regime.*

Data availability: *Data are available from public sources identified in the paper.*

I. INTRODUCTION

Starting January 1, 2005, the European Parliament (Regulation No. 1606/2002) required companies listed on organized exchanges in European Union (EU) countries to prepare their consolidated financial statements using International Financial Reporting Standards

---

We are grateful to John H. Evans III and Wayne B. Thomas (editors), two anonymous reviewers, Jong-Hag Choi, Mark DeFond, Clive Lennox, Dan Simunic, and the participants of the 2010 Annual Conference of CAAA, the 2010 AAA Annual Meeting, the 2011 International Accounting Research Conference at Xiamen University, the research workshops at Chinese University of Hong Kong, City University of Hong Kong, and The University of Hong Kong for their helpful comments and suggestions. We also thank Quan Chen, Hao Li, and Xuejiao Liu for their research assistance. We acknowledge financial support from our respective universities. Any errors are our own responsibility.

(IFRS).[1] Since then, the accounting profession and the academic literature have paid considerable attention to the economic consequences of IFRS adoption. This study adds to the literature by examining whether and how IFRS adoption impacts audit fees.

A number of empirical studies examine whether the quality of financial reporting improves subsequent to IFRS adoption. Using an international sample from 21 countries, Barth et al. (2008) find that firms voluntarily adopting IFRS generally experience less earnings management, more timely loss recognition, and greater value-relevance than do matched sample firms applying local generally accepted accounting principles (GAAP). Chen et al. (2010) examine mandatory IFRS adoption of firms from 15 EU member states and find less earnings management toward a target, a lower magnitude of absolute discretionary accruals, and higher accruals quality after mandatory IFRS adoption. However, these authors and Ahmed et al. (2009) also suggest that firms engage in more earnings smoothing and recognize large losses in a less timely manner in post-IFRS adoption periods. Several other studies that examine the effects of voluntary or mandatory IFRS adoption on accounting quality within a single country provide mixed evidence (e.g., Eccher and Healy 2003; Bartov et al. 2005; Van Tendeloo and Vanstraelen 2005; Hung and Subramanyam 2007; Jeanjean and Stolowy 2008; Paananen and Lin 2009).

In addition to studies on the effect of IFRS adoption on financial reporting quality, another strand of research examines a broader range of economic consequences of IFRS adoption. Evidence indicates that IFRS adoption leads to lower cost of equity capital (Daske et al. 2009; Li 2010), higher market liquidity (Leuz and Verrecchia 2000; Drake et al. 2010), more investment flows through foreign mutual funds (Covrig et al. 2007), more favorable terms in private debt contracting (Kim et al. 2011), greater analyst coverage (Kim and Shi 2012b), and lower stock return synchronicity (Kim and Shi 2012a). Several studies (e.g., Comprix et al. 2003; Christensen et al. 2008; Pae et al. 2008; Armstrong et al. 2010) seek to address whether the benefits of IFRS adoption outweigh the associated costs by examining market reactions to the events leading to IFRS adoption. These studies yield mixed evidence on whether market participants perceive an overall net benefit from IFRS adoption.

The aforementioned studies shed light on the ongoing debate regarding the merits of adopting IFRS. However, very few studies directly examine the costs associated with IFRS adoption. Our study aims to provide systematic evidence on the cost side of mandate IFRS adoption, with a focus on audit costs. Specifically, we investigate whether the EU decision to mandate adoption of IFRS impacts fees paid to auditors for their financial statement audits (henceforth, audit fees). In addition, we examine the channels through which IFRS adoption leads to changes in audit fees.

Since Simunic (1980), many studies have examined cross-sectional determinants of audit fees within a country. These studies find that audit fees are primarily determined by client size, audit task complexity, and potential legal liability or litigation risk (e.g., Craswell et al. 1995; Simunic and Stein 1996). Our study extends the previous single-country studies to an international setting, where mandatory IFRS adoption by EU countries leads to a shift in disclosure regime. This shift implies not only a change in audit task complexity, but also a change in financial reporting quality across countries with different legal regimes. We take advantage of this unique setting to assess how such changes work together to affect audit fees.

To guide our hypothesis development and interpretation of empirical results, we first develop a simple analytical model in which audit task complexity, financial reporting quality, and legal regime play critical roles in the production and pricing of audit services. We then test the model's predictions concerning the relation between IFRS adoption and audit fees. To further understand the audit fee effect of IFRS adoption, we also test the model's predictions of how the relation between IFRS adoption and audit fees varies with a country's institutional factors. In so doing, we consider three types of institutional factors: (1) the increase in audit complexity arising from IFRS adoption, (2) the change in financial reporting quality brought about by IFRS adoption, and (3) the strength of a country's legal regime.

---

[1] The last decade has witnessed a growing trend of IFRS adoption around the world, with more than 100 countries now requiring or permitting IFRS for their domestically listed companies. In 2002, the International Accounting Standards Board and the Financial Accounting Standards Board in the U.S. embarked on a joint program, known as the Norwalk Agreement, to make the U.S. GAAP and IFRS fully compatible.

For our empirical tests, we employ a difference-in-differences design to control for the general trend or changes in the economic environment unrelated to IFRS adoption. Specifically, we use as the control sample non-adopter firms from Organization for Economic Co-operation and Development (OECD) countries in which IFRS had not been mandated up to 2008. Our final sample consists of 2,860 firm-years from 11 EU countries in the treatment sample and 9,052 firm-years from three OECD countries (Japan, Canada, and the U.S.) in the control sample for which we have observations during both the pre-IFRS adoption period (hereafter, the pre-IFRS period) and the post-IFRS adoption period (hereafter, the post-IFRS period). Unless otherwise specified, we use the term *pre-IFRS period* to refer to $t-1$ and *post-IFRS period* to refer to $[t+1, t+3]$, where t is the adoption year.[2]

Our empirical results can be summarized as follows. First, we find that audit fees increase from the pre-IFRS period to the post-IFRS period for both the IFRS adopter firms in the treatment sample (EU countries) and the non-adopter firms in the benchmark control sample (non-EU OECD countries), but this fee increase is larger in magnitude for IFRS adopter firms than for non-adopter firms. More importantly, we find that the incremental fee increase for the adopter firms (over and above the audit fee change for the non-adopter firms) is highly significant at the 1 percent level. The above results, taken together, lead us to conclude that IFRS adoption causes a significant increase in audit fees. Second, we find that this audit fee increase for IFRS adopter firms from the pre-IFRS period to the post-IFRS period, which we refer to as the IFRS-related audit fee premium, is positively related to the increase in audit complexity brought about by IFRS adoption. Third, we find that the IFRS-related audit fee premium decreases with the improvement in financial reporting quality brought about by IFRS adoption. Fourth, we find some evidence that the IFRS-related audit fee premium decreases with the strength of a country's legal regime. The above results hold after controlling for the concurrent reforms in corporate governance and enforcement mechanisms. This suggests that the audit fee premium documented in this paper is primarily driven by IFRS adoption *per se*, rather than by concurrent reforms that may also affect audit fees.

This study makes several contributions to the literature. First, it is one of the few studies that directly examine the cost side of IFRS adoption with a focus on audit fees. A study conducted by the Institute of Chartered Accountants in England and Wales (ICAEW 2007) on behalf of the European Commission suggests that EU companies ranked increased audit costs as one of their largest IFRS-related costs. A small number of concurrent academic studies examine the effects of IFRS adoption on audit fees in single country settings (Degeorge et al. 2008; Griffin et al. 2009; Lin and Yen 2010; Vieru and Schadewitz 2010). These studies provide consistent evidence that audit fees increase in the post-IFRS period. Using audit fee data from 11 EU countries and employing a difference-in-differences approach, we provide large-sample evidence on the average magnitude of the audit fee premium associated with IFRS adoption. Specifically, we find that, on average, the audit fee increase is 5.44 percent greater for the adopter firms, compared to that for the non-adopter firms in our control sample. Moreover, our cross-country study sheds light on how the institutional features of different countries, including legal environments and pre-IFRS local GAAP characteristics, affect the audit fee premium associated with IFRS adoption. The findings of this paper should therefore be of substantial interest to regulators and policy makers, including those in countries that have not yet decided to move toward IFRS.

---

[2] Since our focus is on mandatory IFRS adoption, we exclude firms that started IFRS reporting either prior to the mandatory adoption year ("voluntary adopters") or after the mandatory adoption year ("late adopters"). The EU mandated IFRS adoption for each financial year starting on or after January 1, 2005. Adoption year t in this study is 2005 (2006) for firms with a December (non-December) fiscal year-end. Note that the year to which Worldscope assigns financial data is the year in which the company's fiscal year ended. Section III provides a detailed discussion on our choice of pre- and post-IFRS windows.

Second, this study contributes to the audit-pricing literature. To the best of our knowledge, our study is the first to provide systematic evidence on the two channels of audit complexity and financial reporting quality through which accounting standards and their changes affect audit fees. More specifically, IFRS adoption involves not only an upward shift in audit complexity, which increases audit fees, but also a simultaneous improvement in financial reporting quality, which reduces audit fees. Our empirical results suggest that both factors play important roles in explaining cross-sectional variations in audit fee changes brought about by IFRS adoption.

The rest of the paper is organized as follows. Section II develops a theoretical audit fee model and formulates empirical hypotheses based on the model's predictions. Section III specifies empirical models for hypothesis testing. Section IV describes our sample and presents descriptive statistics. Section V reports our main empirical results, while Section VI presents additional sensitivity analyses. Section VII concludes.

II. THEORY AND HYPOTHESIS DEVELOPMENT

To gain insight into the effect of IFRS on audit fees, we build an audit fee model that is similar in spirit to the audit fee models in Liu and Simunic (2005) and Choi et al. (2008, 2009). For any given auditor, his or her objective (decision problem) is to choose the audit effort $e \in (0, 1)$ that minimizes total audit cost, which is the sum of the expected legal liability cost and the auditor's effort cost:

$$\underset{e \in (0,\,1)}{\text{Minimize}}\,\text{Total-Audit-Cost} = (1-q)[c(1-e)][r(1-e)]l + ke^2, \tag{1}$$

where:

- $q \in (0, 1)$ denotes the financial reporting quality conditional on a country's reporting regime (GAAP), which is defined as the probability of financial statements containing no misstatement conditional on the reporting regime;
- $c \in (0, 1)$ refers to the complexity of the audit;
- $e \in (0, 1)$ represents the auditor's effort;
- $r \in (0, 1)$ refers to the strength of a country's legal environment in determining the auditor's legal liability conditional on audit failure;
- $l > 0$ refers to the legal payment the auditor makes to the client if the auditor is found liable in court; and
- $k > 0$ is the auditor's effort cost parameter.

To interpret the economic meaning of the audit fee, first note that audit risk refers to the risk that an auditor fails to discover and report a material misstatement in a company's financial report, and is a function of material misstatement and detection risk (IAASB 2009). Consistent with this concept, audit risk in our model corresponds to $(1-q)[c(1-e)]$, where $(1-q)$ represents the risk of material misstatements, defined as the probability of client misreporting (i.e., failure to comply with GAAP), and $c(1-e)$ represents the detection risk, defined as the probability of the auditor's failure to discover and report misstatements *conditional on* the financial report being misstated. The detection risk is increasing in audit complexity c and decreasing in the auditor's effort e.

Second, note that the auditor's engagement risk represents the overall risk associated with an audit engagement. This engagement risk consists of two components, audit risk and litigation risk, and is formally represented by $[(1-q)c(1-e)][r(1-e)l]$ in our model. The litigation risk component, $r(1-e)$, is the probability of the auditor being held liable in court in the event of audit failure, which is increasing in the strength of the country's legal regime r and decreasing in the auditor's effort e. Hence, $[(1-q)c(1-e)][r(1-e)l]$ as a whole represents the auditor's *expected* legal liability associated with an audit engagement. Finally, ke^2 is the auditor's effort cost, which is increasing and convex in effort e.

The auditor's effort is determined by the first-order condition:

$$e^* = (1-q)crl/[(1-q)crl + k].$$

Specifically, the auditor's effort is a function of the reporting quality q, audit complexity c, and the strength of the legal regime r.

In a competitive audit market, the audit fee equals the total audit cost in equilibrium; that is:

$$f = (1-q)rc(1-e^*)^2 l + ke^{*2}.$$

Since $\partial f/\partial r = (1-q)c(1-e^*)^2 l > 0$, $\partial f/\partial c = (1-q)r(1-e^*)^2 l > 0$, and $\partial f/\partial q = -rc(1-e^*)^2 l < 0$, we obtain the following results:

Observation 1: The audit fee is increasing in the strength of the legal regime r and in audit complexity c, but decreasing in financial reporting quality q.

One implication of Observation 1 is that the audit fee decreases with the quality of financial reporting. The intuition behind this result is clear: given GAAP, the higher the quality of a financial report (which means less likelihood of financial misstatements), the lower the audit risk an auditor faces, which leads to a lower audit fee.

To examine how IFRS adoption changes the audit fee, we note that IFRS adoption has two audit-related effects. First, the adoption of IFRS may improve financial reporting quality, that is, reduce financial misstatements conditional on the reporting regime, thereby reducing audit risks. IFRS is generally considered to be superior to former local accounting standards. Proponents of IFRS claim that IFRS adoption leads to increased and higher quality disclosures that better reflect a firm's economic conditions. They argue that, compared with former local GAAP in most countries, IFRS is more principles-based, emphasizing a "true and fair view" in both letter and spirit, and incorporating into financial statements the effects of economic events on firm performance in a timelier manner (Coopers & Lybrand 1993; Dumontier and Raffournier 1998; Alexander and Archer 2001).[3] More specifically, the adoption of IFRS may reduce financial misstatements by improving management's accounting decisions and measurements. To the extent that IFRS fills voids in the local standards and provides comprehensive guidelines on accounting issues, it can lead to better judgments and, thus, fewer misstatements or better compliance with the fair presentation principle of GAAP to reflect the firm's underlying economics.[4] Moreover, accounting choices and judgment are often allowed for an accounting issue. IFRS provides more practical guidelines to limit opportunistic management discretion in determining accounting amounts, thus leading to fewer misstatements or better compliance with accounting standards that require professional judgment (Barth et al. 2008). In summary, the comprehensiveness and quality of IFRS guidelines have positive effects on reporting quality, as they improve management accounting decisions and reduce judgment errors in complying with GAAP, particularly the fair presentation principle. The improved financial reporting quality tends to reduce audit risk and the audit fee.

---

[3] Skeptics, on the other hand, argue that IFRS adoption is unlikely to enhance accounting quality unless it is accompanied by a wide range of complementary changes in infrastructure (Ball 2006). In addition, the inherent flexibility in principles-based standards could provide more room for firms to manage earnings. This effect on client misreporting, however, can be mitigated by extensive practical guidelines to help firms comply with such a standard.

[4] In most countries, compliance with GAAP is not narrowly defined in the accounting framework as compliance only with specific accounting provisions. It also includes compliance with the fair presentation principle of GAAP. Managers/auditors cannot avoid litigation simply by blaming GAAP for lacking specific provisions or practical guidelines. Failure to fairly present the firm's economic conditions when judgment is required constitutes misstatements and violation of GAAP, subject to the court's decision.

Second, IFRS adoption increases the complexity of an audit. Since IFRS is comprehensive, fair-value oriented, and principles-based, using IFRS generally requires accountants and auditors to make more complex estimates and to use greater professional judgment (KPMG 2007; Deloitte 2008).[5] As shown in Observation 1, improved financial reporting quality reduces the audit fee, but increased audit complexity increases it. Therefore, the effect of IFRS adoption on audit fees is determined by which of the above two forces is dominant. Our analysis yields the following observation.

Observation 2: IFRS adoption, which increases both financial reporting quality q and audit complexity c, leads to an increase (decrease) in audit fees if the positive effect of the increase in audit complexity dominates (is dominated by) the negative effect of improved financial reporting quality on the audit fee. Specifically, IFRS adoption increases (decreases) the audit fee if $(1-q)\Delta c > c\Delta q$ (if $(1-q)\Delta c < c\Delta q$),where Δ denotes the change brought about by IFRS adoption.

Proof: See Appendix A.

Observation 2 indicates that IFRS adoption can lead to an increase or decrease in audit fees, depending on whether an increase in audit complexity or an increase in financial reporting quality is the dominant factor in determining the audit fee change.[6] Since we cannot specify *a priori* the direction of the impact of IFRS adoption on audit fees, we formulate the following null hypothesis:

H1: IFRS adoption has no impact on audit fees.

To facilitate the discussion below, we now summarize the subsequent results of empirical tests for H1. As reported later in Table 5, these results show that IFRS adoption leads to an increase in audit fees. According to Observation 2, these empirical results suggest that $(1-q)\Delta c > c\Delta q$ holds; that is, the positive effect of increased audit complexity on audit fees dominates the negative effect of improved reporting quality, leading to an IFRS-related increase in the audit fee or audit fee premium.

We next examine how this audit fee premium associated with IFRS adoption varies with a number of institutional factors. First, we examine the effect of increased audit complexity arising from IFRS adoption. We find that:

---

[5] For a small subset of cross-listed clients, the increase in audit complexity associated with IFRS adoption may be partially offset by a benefit derived from reduced reconciliation to foreign countries' GAAP if the cross-listed foreign country has also adopted IFRS. Out of the 833 firms in our final treatment sample, 45 are identified as being cross-listed in foreign countries that also mandated IFRS before 2008. The untabulated results for our test variables remain qualitatively unchanged after excluding these 45 firms.

[6] While our discussion focuses on the situation in which IFRS leads to an improvement in financial reporting quality q, our analytical results (observations) encompass situations in which q can increase or decrease. If IFRS adoption causes deterioration in financial reporting quality, then the condition $(1-q)\Delta c > c\Delta q$ in Observation 2 always holds, which means that the IFRS-related audit fee change will always be positive and is attributable to both reduced financial reporting quality and increased audit complexity. H3 specifically addresses the relation between the audit fee change and the cross-country variation in the change of reporting quality brought about by IFRS adoption.

$$\partial \Delta f / \partial \Delta c = \partial [f(q_{IFRS}, c_i + \Delta c) - f(q_i, c_i)] / \partial \Delta c > 0,$$

where the subscript i refers to country i. This means that, *ceteris paribus*, the greater the increase in audit complexity (i.e., greater Δc), the greater the IFRS-related audit fee premium. Second, we examine how the IFRS-related audit fee premium varies with the change in financial reporting quality brought about by IFRS adoption. We find that:

$$\partial \Delta f / \partial \Delta q = \partial [f(q_i + \Delta q, c_{IFRS}) - f(q_i, c_i)] / \partial \Delta q < 0,$$

which means that, *ceteris paribus*, the greater the improvement in financial reporting quality brought about by IFRS adoption (i.e., greater Δq), the smaller the audit fee premium. We summarize these results as follows.

Observation 3: The audit fee premium associated with IFRS adoption is increasing with the increase in audit complexity arising from IFRS adoption, and decreasing with the improvement in financial reporting quality brought about by IFRS adoption.

Based upon the predictions in Observation 3, we test the following hypotheses.

H2: *Ceteris paribus*, the audit fee premium associated with IFRS adoption is increasing with the increase in audit complexity brought about by IFRS adoption.

H3: *Ceteris paribus*, the audit fee premium associated with IFRS adoption is decreasing with the improvement in financial reporting quality brought about by IFRS adoption.

Finally, we examine how the audit fee premium associated with IFRS adoption varies with a country's legal regime. In this analysis, we assume that $(1 - q)\Delta c > c\Delta q$, which means that the increase in audit complexity dominates any improvement in financial reporting in determining the audit fee change, since we observe an overall positive audit fee change after IFRS adoption (see the discussion following H1). We derive:

$$\partial df / \partial r = (\partial df / \partial r)|_{e=e*} + (\partial df / \partial e)(\partial e / \partial r).$$

The first component, $(\partial df / \partial r)|_{e=e*} > 0$, represents the direct positive effect of a stronger legal regime on the audit fee premium, *with effort level being fixed*. The intuition for the positive sign on this first component is that, when the auditor's effort is fixed, a stronger legal regime experiences a larger IFRS-related audit fee premium because the auditor faces greater legal liability in a stronger legal regime. The second component, $(\partial df / \partial e)(\partial e / \partial r) < 0$, represents the negative effect of greater auditor effort on the audit fee premium. The economic intuition for the negative sign on the second component is that auditors are induced to expend greater effort in a stronger legal regime, which has a negative effect on the auditor's expected legal liability cost and, thus, reduces the IFRS-related audit fee premium. To summarize, the effect of the legal regime on the IFRS-related audit fee premium, i.e., the sign of $\partial df / \partial r$, depends on which of the two forces mentioned above is dominant. Our analysis yields the following results:

Observation 4: Assume that $(1 - q)\Delta c > c\Delta q$ holds. The audit fee premium associated with IFRS adoption decreases (increases) with the strength of a country's legal regime if the incentive effect of a stronger legal regime on auditor effort is sufficiently large (small). Specifically, $\partial df / \partial r < 0 (\partial df / \partial r > 0)$ when the strength of the legal regime exceeds (falls below) a threshold, that is $r > k / cl(1 - q) (r < k / cl(1 - q))$.

Proof: See Appendix A.

Observation 4 shows that if the legal regime, r, is sufficiently strong, then the incentive effect on the auditor's expected liability costs becomes the dominant factor, leading to an overall reduction in the IFRS-related audit fee premium in a stronger legal regime. However, because the condition in Observation 4 is *a priori* unknown, we formulate the following hypothesis in null form:

> **H4:** The audit fee premium associated with IFRS adoption in countries with strong legal regimes is the same as that in countries with weak legal regimes.

III. EMPIRICAL PROCEDURES

Research Design for Testing H1

To assess the overall effect of mandatory IFRS adoption on audit fees (H1) for adopter firms in EU countries, we employ a difference-in-differences design, using non-adopter firms in selective non-EU countries as the benchmark. The difference-in-differences design is used to control for changes unrelated to IFRS adoption in the form of a general trend or concurrent changes in audit fees that may also be experienced by the non-adopter firms in the control sample.

We choose our benchmark control sample of firms from non-EU OECD countries that had not mandated IFRS as of 2008. Non-EU OECD countries have well-developed capital markets and are at a stage of economic development similar to those of EU countries, making them a reasonable control group for our tests. Specifically, we estimate the following regression model:

$$\begin{aligned} AUDFEE = {} & \beta_0 + \beta_1 POST + \beta_2 POST*TREAT + \sum \delta_k FSCONTROL_k + Industry\ Indicators \\ & + Country\ Indicators + \varepsilon, \end{aligned} \tag{2}$$

where:

$AUDFEE$ = natural log of the audit fee in thousands of euros;
$TREAT$ = 1 for firms in the treatment sample (i.e., mandatory adopter firms in EU countries), and 0 for firms in the benchmark control sample (i.e., non-adopter firms in non-EU OECD countries); and
$POST$ = 1 for the post-IFRS period, and 0 for the pre-IFRS period.

For firms in the control sample, we assign the pseudo-adoption year 2005 (2006) for firms with a December (non-December) fiscal year-end (to be consistent with the IFRS adoption pattern in the treatment firms). The term *FSCONTROL* denotes firm-specific control variables. Our model specification includes country-specific indicators, which fully control for *fixed* differences between treatment and control countries (Low 2009, 478; Bertrand and Mullainathan 2003, 1057). We also include industry fixed effects.

In Equation (2), the coefficient β_1 captures the audit fee change for non-adopter firms in the control sample from the pre-(pseudo)-adoption period to the post-(pseudo)-adoption period. The coefficient of interest is β_2, which captures the *incremental* change in audit fees from the pre-IFRS period to the post-IFRS period in the treatment sample relative to the change in the control sample. H1 in *null* form translates to predicting that $\beta_2 = 0$. Appendix B provides detailed definitions for all variables included in Equation (2).

We include 14 firm-specific controls (*LNTA*, *INVREC*, *NBS*, *NGS*, *MB*, *LOSS*, *LEV*, *QUICK*, *SPECIAL_ITEM*, *QUALIFIED*, *MERGE*, *FINANCE*, *BIG4*, and *CROSS*). The variables *LNTA* and *INVREC* are proxies for client size and client complexity, respectively (Simunic 1980; Francis 1984). Because operationally or geographically diversified firms may require more complex audits, we include the number of business segments (*NBS*) and the number of geographical segments

(*NGS*) as additional proxies for client complexity (Simunic 1980; Choi et al. 2008). Following the audit fee literature (Francis 1984; Seetharaman et al. 2002; Hay et al. 2006), we include *LOSS*, *LEV*, *QUICK*, *SPECIAL_ITEM*, and *QUALIFIED* to measure client-specific litigation risks borne by auditors. Similar to Ashbaugh et al. (2003), we include two indicator variables, *MERGE* and *FINANCE*, to capture the demand for additional audit and consulting services associated with business combinations and financing activities. We expect the coefficients for all the above firm-specific control variables except *QUICK* to be positive, since the literature shows that audit fees are positively related to client size, client complexity, and client-specific risk factors. We expect the coefficient of *QUICK* to be negative, since a low *QUICK* ratio is associated with higher financial risk (Francis 1984). The market-to-book ratio (*MB*) is included, but the relation between *MB* and audit fees is unclear, since it is associated with audit complexity and firm risk, as well as firm performance (Ashbaugh et al. 2003).

We include the Big 4 indicator variable (*BIG4*) to capture a Big 4 auditor fee premium (DeFond et al. 2000; Choi et al. 2008). Choi et al. (2009) find that auditors charge higher fees for firms that are cross-listed in countries with stronger legal regimes than they do for non-cross-listed firms. We therefore control for any cross-listing effect by including an indicator variable, *CROSS*, which equals 1 for cross-listed firms, and 0 otherwise.

To estimate Equation (2), we pool the pre- and post-IFRS data. One problem we face is that most of the firm-specific control variables are accounting-based measures. This means that, for IFRS adopter firms in our treatment sample, these variables are measured following local GAAP in the pre-IFRS period and IFRS in the post-IFRS period. This measurement difference may cause the coefficients on the accounting measures to differ between the pre- and post-IFRS periods. Thus, it could be problematic to pool data from pre- and post-IFRS periods. To address this measurement problem, we restrict our pre-IFRS period to year $t-1$ and use restated numbers under IFRS for accounting-based, firm-specific control variables, where year t is the adoption year. IFRS 1 (*First-Time Adoption of International Financial Reporting Standards*) requires firms to apply IFRS retrospectively to the year prior to IFRS adoption to establish comparative financial statements in year t. This regulatory requirement provides us with one year of data in the pre-IFRS era with accounting measures that are recalibrated by firms following IFRS.[7]

Our post-IFRS period covers three years $[t+1, t+3]$, excluding the adoption year t. We exclude the adoption year t in our main analysis to alleviate any potential concern that our results are driven by temporary transitional effects.

Research Design for Testing H2, H3, and H4

To test the impact of institutional factors on the audit fee premium associated with IFRS adoption (H2–H4), we estimate the following model:

$$\begin{aligned} AUDFEE = {} & \beta_0 + \beta_1 POST + \beta_2 POST*TREAT + \beta_3 POST*TREAT*\Delta COMPLEXITY \\ & + \beta_4 POST*TREAT*\Delta QUALITY + \beta_5 POST*TREAT*Legal\ Regime \\ & + \sum \delta_k FSCONTROL_k + Industry\ Indicators + Country\ Indicators + \varepsilon, \end{aligned} \qquad (3)$$

where *TREAT* and *POST* are as defined in Equation (2) and $\Delta COMPLEXITY$ refers to the change (increase) in audit complexity arising from IFRS adoption. To obtain an empirical proxy for

---

[7] We thank an anonymous referee for bringing this measurement issue to our attention. Another benefit of starting the sample period from $t-1$ is to avoid the effect of SOX-related reforms on the audit fee change in the control sample. The untabulated results suggest a large increase in audit fees from $t-2$ to $t-1$ in the U.S. sample, which is likely due to SOX Section 404(b), which requires auditors to express opinions on client firms' internal controls for fiscal years ending on or after November 15, 2004.

$\Delta COMPLEXITY$, we first measure the extent to which (pre-IFRS) local GAAP deviates from IFRS. Since IFRS is more comprehensive, principles-based, and fair-value-oriented, it involves more complex planning, tests, and judgment on the part of auditors. As such, a large deviation between IFRS and local GAAP implies that IFRS adoption causes a large increase in audit complexity.

Ding et al. (2007) classify and quantify the difference between local GAAP and IFRS along two dimensions, *Absence* and *Divergence*. The *Absence* score is based on the number of accounting rules regarding particular accounting issues that are missing in (pre-IFRS) local GAAP but that are explicitly stipulated in IFRS. The *Divergence* score is based on the number of accounting rules regarding the same accounting issue that differ between IFRS and (pre-IFRS) local GAAP. In this study, $\Delta COMPLEXITY$ is computed as the natural log of the sum of the *Absence* and *Divergence* scores, since both lead to an increase in audit complexity. H2 states that the audit fee premium associated with IFRS adoption is increasing with the change in audit complexity brought about by IFRS adoption, which translates to a positive coefficient for $POST * TREAT * \Delta COMPLEXITY$ (i.e., $\beta_3 > 0$).

The variable $\Delta QUALITY$ refers to the change in financial reporting quality brought about by IFRS adoption. We use three different measures to empirically capture $\Delta QUALITY$. Our first measure is based on the previously described comparison of IFRS versus pre-IFRS local GAAP. Although IFRS deviates from local GAAP along the two dimensions of *Absence* and *Divergence*, for reasons we describe below, our measure of the change in reporting quality focuses only on the *Absence* dimension. Specifically, we use the natural log of $(1 + Absence)$, denoted $\Delta GAAPQ$, to measure the change (improvement) in GAAP quality brought about by IFRS adoption.[8] Since a high *Absence* score implies a less developed pre-IFRS local GAAP, *ceteris paribus*, a higher level of *Absence* in the pre-IFRS period implies a greater improvement in reporting quality in the post-IFRS period.

We do not include *Divergence* when measuring the change in reporting quality associated with IFRS adoption because *Divergence* does not have a clear implication for whether domestic GAAP is superior or inferior to IFRS (Ding et al. 2007).[9] Given the ambiguity in the relation between *Divergence* and reporting quality, we construct two discretionary accrual measures of the change in reporting quality brought about by IFRS adoption. Prior studies (e.g., Jones et al. 2008) identify discretionary accruals as an important red flag for material misstatement and fraud, which are particularly relevant to the duties of an auditor. The first discretionary accrual measure, denoted *DA1*, is the residual from the cross-sectional Jones (1991) model. The second measure, denoted *DA2*, is the residual from the cross-sectional Dechow and Dichev (2002) model augmented by the fundamental variables from the modified Jones models. More specifically, we measure $\Delta QUALITY$ through $\Delta|DA1|$ and $\Delta|DA2|$, that is, the changes in the country's median values of the absolute discretionary accruals from the pre-IFRS period ($t-1$) to the post-IFRS period ($[t+1, t+3]$). In constructing these two variables, we use only observations from our final audit fee sample. We multiply $\Delta|DA1|$ and $\Delta|DA2|$ by -1 so that higher values indicate greater improvements in financial reporting quality. Appendix C provides more detail on the construction of *DA1* and *DA2*.

In summary, we measure the reporting quality changes, $\Delta QUALITY$ in Equation (3), using three different proxies: $\Delta GAAPQ = ln(1 + Absence)$, $(-1) * \Delta|DA1|$, and $(-1) * \Delta|DA2|$. H3 predicts that the IFRS-related audit fee premium decreases with the improvement in financial reporting quality brought about by IFRS adoption, which translates to a negative coefficient for $POST * TREAT * \Delta QUALITY$ (i.e., $\beta_4 < 0$).

---

[8] We use $-ln(1 + Absence)$ to proxy for GAAP quality. Since *Absence* becomes 0 in the post-IFRS period, the change in GAAP quality is captured by $0 - [-ln(1 + Absence)] = ln(1 + Absence)$.

[9] On the one hand, one can argue that the international standard-setting process is intended to design a set of internationally acceptable high-quality financial reporting standards. Hence, IFRS should be generally superior to local standards, and any deviation may be viewed as an indication of low-quality reporting. On the other hand, one can argue that local accounting standards that deviate from IFRS are more customized to the local business practices and legal environment and, hence, provide better information to local stakeholders (Ding et al. 2007).

Finally, we examine the impact of legal regime on the IFRS-related audit fee premium. The strength of legal regime in Equation (3) is first proxied by *WINGATE*, which is the natural log of the Wingate (1997) litigation index. The Wingate index has been widely used in prior audit fee studies (e.g., Choi et al. 2008, 2009), and is based on surveys of partners in auditing firms regarding auditor litigation risk and, hence, captures those dimensions of a legal environment that are most relevant to auditing practices. However, the Wingate index may not capture recent changes in the legal environment. We therefore employ two additional measures of the strength of legal regimes. We include a more recent measure, *ENFORCE*, which refers to the aggregate public enforcement index from La Porta et al. (2006). In addition, La Porta et al. (1998) document that common law countries generally have stronger legal protection for investors than civil law countries. We therefore include an indicator variable, *LAW*, which equals 1 for countries with a common law legal origin, and 0 otherwise. We consider *LAW* and *ENFORCE* together in our regression analyses to comprehensively capture the legal environment in which managers operate their businesses and auditors perform their professional services.

In summary, legal regime in Equation (3) is measured by two proxies: (1) *WINGATE* and (2) both *LAW* and *ENFORCE*. Our null hypothesis, H4, translates to a prediction that $\beta_4 = 0$.

IV. SAMPLE AND DESCRIPTIVE STATISTICS

We initially obtain from Worldscope a sample of 29,206 firm-years from 14 EU countries over the period 2004–2008. To test our hypotheses, we exclude (1) firm-year observations for which information about the chosen accounting standards is missing, ambiguous, or coded as U.S. GAAP; (2) firms that belong to banking, insurance, or other financial industries (with a Worldscope general industry classification of 04, 05, or 06); (3) firms that adopted IFRS prior to the mandatory adoption year (voluntary adopters); (4) firms that adopted IFRS after the mandatory adoption year (late adopters); (5) firm-year observations with missing audit fee data; (6) firm-year observations lacking the data required to compute other firm-specific control variables; (7) firms without sufficient information to clearly identify their IFRS adoption year; and (8) firm-year observations falling outside our sample period of [*t*–1, *t*+3]. Finally, we require each firm to have data in the adoption year *t*, the pre-adoption year *t*–1, and at least one observation in the post-IFRS years [*t*+1, *t*+3] to minimize the impact of changes in sample composition on our results. The final treatment sample consists of 3,693 (2,860) firm-year observations for 11 EU countries if we include (exclude) the adoption year *t*.

Next, to construct our control sample, we begin with firm-year observations from non-EU member countries in the OECD that had not mandated IFRS adoption up to 2008. This requirement leads to an initial sample of 73,114 observations over the period 2004–2008 from seven countries (Canada, Chile, Japan, Mexico, South Korea, Turkey, and the U.S.). We follow sample-selection procedures similar to those used for the treatment sample. The final control sample consists of 11,903 (9,052) firm-year observations from three countries (Japan, Canada, and the U.S.) if we include (exclude) the pseudo-adoption year *t*.[10] Table 1 provides detailed information on our sample selection.

Table 2 reports the pattern of IFRS adoption over the period 2005–2008 across 14 EU countries. These statistics are based on a comprehensive EU sample before we impose the non-missing data requirements for audit fees and firm-specific control variables. We use data field 07536 in Worldscope to identify accounting standards followed by each firm in each year. This data

---

[10] Seven OECD countries had not mandated IFRS adoption as of 2008. Audit fee information is mostly unavailable for Chile, Mexico, South Korea, and Turkey, which leaves three countries in the final control sample. The relatively small number of observations for Japan is due to limited audit fee data prior to 2007.

TABLE 1
Sample Selection[a,b,c]

	Treatment Sample (EU Countries)	Control Sample (OECD Countries)
Initial sample (firm-year observations) from Worldscope, 2004–2008	29,206	73,114
Subtract:		
Firm-year observations for which information about the chosen accounting standard is missing or ambiguous	(758)	
Firms that belong to banking, insurance, or other financial industries	(6,244)	(10,584)
Firms that started IFRS reporting prior to the mandatory adoption year (voluntary adopters)	(3,332)	(344)
Firms that started IFRS reporting after the mandatory adoption year (late adopters)	(6,360)	
Firm-year observations with missing audit fee data	(5,645)	(31,661)
Firm-year observations lacking data required to compute firm-specific control variables	(793)	(7,170)
Firms without sufficient information to identify their IFRS adoption year *t*	(488)	
Firm-year observations falling outside our sample period of [$t-1$, $t+3$]	(336)	(1,303)
Firms that do not have data available in both the pre- and post-adoption periods	(1,557)	(10,149)
Final sample including adoption year *t*	3,693	11,903
Final sample excluding adoption year *t*	2,860	9,052

[a] The initial sample consists of 14 EU countries in the treatment group and seven countries in the control group (Canada, Chile, Japan, Mexico, South Korea, Turkey, and the U.S.). The countries in the control group are selected using the following two criteria: (1) the country belongs to the OECD, and (2) the country had not mandated IFRS adoption up to 2008. Further sample-selection procedures result in a final sample of 11 EU member countries and three OECD countries. See Table 3 for details of the final sample composition.

[b] The year to which Worldscope assigns financial data is the year in which the company's fiscal year ended. Thus, the mandatory adoption year for firms with a December (non-December) fiscal year-end is 2005 (2006). We assign the pseudo-adoption year of 2005 (2006) for firms with a December (non-December) fiscal year-end in the control sample.

[c] Since the control sample has not mandated IFRS up to 2008, firms in the control sample are identified as voluntary adopters if they choose IFRS in any year in the sample period.

field includes a total of 23 categories. In the main test, we follow Daske et al. (2009) to use the strict coding for IFRS adoption, which consists of only Worldscope categories 02 ("International Standards") and 23 ("IFRS").[11]

As shown in Table 2, the adoption of IFRS by the end of 2006 is incomplete, with the U.K. having the lowest adoption rate (45 percent), followed by Ireland (63 percent). The reason is that Regulation No. 1606/2002 of the European Parliament allowed the following types of firms to postpone IFRS adoption: (1) firms listed on less-regulated markets (e.g., the Alternative Investment Market in London); (2) firms reporting non-consolidated reports; (3) firms publicly traded in a

---

[11] The results are qualitatively similar when we use an alternative coding by Jeanjean and Stolowy (2008) or a comprehensive, less strict coding following Daske et al. (2009, Table 1A, Panel A).

TABLE 2

Distribution of IFRS Adoption 2005–2008

	2005		2006		2007		2008	
Country	**# of Firms**	**% of IFRS**	**# of Firms**	**% of IFRS**	**# of Firms**	**% of IFRS**	**# of Firms**	**% of IFRS**
Austria	19	74%	20	75%	19	84%	17	94%
Belgium	77	70%	78	77%	74	80%	52	88%
Denmark	92	59%	101	81%	103	82%	97	87%
Finland	107	93%	105	100%	101	100%	97	100%
France	651	59%	639	74%	574	78%	461	87%
Germany	376	54%	387	66%	369	70%	289	78%

This table reports the percentage of firms that adopt IFRS during the period of 2005–2008 across 14 EU countries. The initial sample obtained from the Worldscope database consists of 29,206 firm-year observations from 2004 to 2008. We delete (1) firm-year observations with accounting standard information missing, ambiguous, or coded as U.S. GAAP, (2) firms that belong to the banking, insurance, or other financial industries (Worldscope general industry classification of 04, 05, or 06), and (3) firms that started IFRS reporting prior to the mandatory adoption year (voluntary adopters). These selection procedures result in 18,872 firm-year observations for the period 2004–2008, of which 15,378 observations fall in 2005–2008.

non-EU country that uses internationally accepted standards; and (4) firms with only publicly traded debt securities. By the end of 2008, almost all EU publicly listed firms had adopted IFRS.

Table 3 provides descriptive statistics of audit fees and firm characteristics. Panel A of Table 3 presents the mean values of the variables included in Equation (2) for each country and the grand means for the treatment and control samples.[12] We also report the mean for the pre- and post-IFRS periods, separately, for the treatment and control samples. The panel shows that the number of observations varies across countries, with only four observations for Germany and 1,524 observations for the U.K.[13] The sub-period statistics reveal that both the treatment and control

---

[12] We use the 2008 data for the following four variables: the number of business segments (*NBS*), the number of geographical segments (*NGS*), auditor identity (*BIG4*), and cross-listing status (*CROSS*). Worldscope provides only the most recent year (i.e., 2008) information on *BIG4* and *CROSS*. As for *NBS* and *NGS*, Worldscope does not have complete time-series data (with a code of N.A. for at least one firm-year) for 38 percent of our sample firms. More importantly, the over-time variation of the number of segments could be due simply to the change in segment reporting regulations during the 2002–2008 period, rather than actual change in segments. For example, the revised International Accounting Standard 14 on segment reporting adopted by the EU in 2003 is based on the so-called risks and rewards approach, whereas IFRS 8 on segment reporting, adopted by the EU in 2007, is based on the so-called management approach.

[13] Audit fee data are mostly missing prior to 2005 for firms in Germany, which explains the small number of observations from Germany in the final sample after we require firms to have audit fee information both before and after IFRS adoption. Austria, Greece, and Italy drop out of the sample due to missing audit fee data.

Panel A reports the sample mean for each country and the grand means for the treatment and control samples. The final sample consists of 2,860 firm-year observations from 11 EU countries in the treatment group and 9,052 firm-year observations from three OECD countries in the control group. Data from the IFRS adoption year *t* in the treatment sample and the pseudo-adoption year in the control sample are excluded. To avoid the undue influence of outliers, we winsorize all variables (except for variables with natural lower or upper bounds) at the 1st and 99th percentiles.

Panel B reports the Pearson correlations. Correlation coefficients are bold (italic) if they are statistically significant at the 1 percent (5 percent) level.

See Appendix B for variable definitions.

samples experience an increase in audit fees during the sample period, indicating the importance of controlling for the general trend or the concurrent changes in audit fees.[14]

Panel B of Table 3 presents the Pearson correlation coefficients for the audit fee and firm-specific control variables used in our regression analysis. Consistent with prior studies, audit fees (*AUDFEE*) are highly correlated with all variables representing client size, client complexity, and client-specific risk, except for a complexity variable, *INVREC*.

Panel A of Table 4 presents descriptive statistics for our key institutional variables. As shown in the panel, $\Delta COMPLEXITY$ and $\Delta GAAPQ$ vary significantly across our sample countries, providing us with a reasonable cross-country setting in which to assess the impact of these country-level variables on audit fees. The two accrual-based measures of $\Delta QUALITY$, namely $\Delta|DA1|$ and $\Delta|DA2|$, further indicate that the change in financial reporting quality brought about by IFRS adoption is not homogeneous across countries. For example, of the nine countries that have sufficient data to construct $\Delta|DA1|$ measures, only five reveal negative signs on this measure. The negative values of $\Delta|DA1|$ and $\Delta|DA2|$ indicate a decrease in the magnitude of discretionary accruals, reflecting an improvement in financial reporting quality. *WINGATE*, *LAW*, and *ENFORCE* also vary across countries, suggesting that the strength of legal regime differs across EU countries in our treatment sample.

Panel B of Table 4 presents Pearson correlation coefficients between key institutional variables. The variable $\Delta GAAPQ$ is significantly positively correlated with $\Delta COMPLEXITY$. This is not surprising, since both measures contain the *Absence* score, which captures the development of a country's pre-IFRS local GAAP. $\Delta GAAPQ$ is negatively correlated with *WINGATE* and *LAW*, consistent with the view that countries with weak legal regimes tend to have less comprehensive (poorer) pre-IFRS local standards. Since $\Delta|DA1|$ inversely measures the improvement in financial reporting quality, the negative correlations between $\Delta GAAPQ$ and $\Delta|DA1|$, although only suggestive of the underlying relation, indicate that IFRS adoption is associated with a more significant improvement in financial reporting quality in countries with poorer pre-IFRS accounting standards. As expected, the two accrual-based reporting quality change measures, $\Delta|DA1|$ and $\Delta|DA2|$, are significantly and positively correlated with each other. Finally, we note that *LAW* and *ENFORCE* are not significantly correlated with each other, suggesting that they capture different aspects of the strength of legal regime.

V. REGRESSION RESULTS

Test of H1

H1 is concerned with the overall impact of IFRS adoption on audit fees. To test H1, we estimate Equation (2) and report the results in Column (1) of Table 5. Throughout this paper, all reported t-statistics in parentheses are adjusted using robust standard errors corrected for firm-level clustering. All regressions are estimated after removing outliers with absolute studentized residuals greater than 3. As a result, the actual sample size varies slightly across regressions.

As shown in Table 5, Column (1), the coefficient of *POST* is positive and weakly significant at the 10 percent level ($\beta_1 = 0.019$; t $= 1.89$). This suggests that non-adopter firms in the control

---

[14] Worldscope auditor fee data also include nonaudit fees paid to auditors. We note that the SOX-induced significant declines in the provision of nonaudit services had occurred before IFRS adoption (during 2002–2004), and surveys of U.S. and U.K. audit fees (including the audit fee trend report from Audit Analytics in the U.S. and the Audit Fees Survey from the *Financial Director* magazine in the U.K.) indicate that in both countries the declining trend continued but at a slower pace after 2004, and that nonaudit fees leveled off in 2007 and 2008. Insofar as the decline in nonaudit services is a global trend, our difference-in-differences design mitigates the potential confounding effect of nonaudit fees. Nonetheless, we acknowledge this data limitation.

*, **, *** Indicate statistical significance at the 10 percent, 5 percent, and 1 percent levels, respectively.

[a] Refer to Appendix B for variable definitions, and Appendix C for details of the construction of *Δ|DA1|* and *Δ|DA2|*.

[b] "NA" indicates a missing value due to insufficient data to construct the measure.

sample experienced an average 1.92 percent increase in audit fees from year *t*–1 to years [*t*+1, *t*+3]. The coefficient of *POST* ∗ *TREAT*, which captures the incremental fee-increasing effect associated with IFRS adoption in the treatment sample, is significantly positive ($\beta_2 = 0.052$; t = 2.61). These results suggest that a representative firm in countries that mandated IFRS adoption experienced an average 7.36 percent increase in audit fees during the post-IFRS period;[15] this fee increase is 5.44 percent greater than the fee increase that an average non-adopter firm in the benchmark control sample experienced over the same period. These results lead us to reject the null hypothesis of no audit fee impact (H1) in favor of a significant increase in audit fees in the post-IFRS period.

The coefficients of firm-specific control variables are mostly significant with expected signs at the 1 percent level (except *LEV*, *QUALIFIED*, and *FINANCE*). These results are consistent with the findings in prior literature that audit fees are positively associated with client size (*LNTA*), client complexity (*INVREC*, *NBS*, and *NGS*), and client-specific risks (*LOSS*, the inverse of *QUICK*, and

---

[15] The percentage change in audit fees from the pre-IFRS period to the post-IFRS period in the treatment group (7.36 percent) can be obtained by applying exp $(\beta_1 + \beta_2) - 1$.

[a] Observations in year *t* are excluded in Column (1) and included in Column (2), where *t* is the IFRS adoption year for the treatment sample and a pseudo-adoption year for the control sample, and *ADOPT* equals 1 for the adoption year, and 0 otherwise. Refer to Appendix B for the definitions of the other variables.

[b] Observations with absolute studentized residuals greater than 3 are deleted. The reported t-statistics are based on standard errors clustering on the firm dimension.

SPECIAL_ITEM). We find that the market-to-book ratio (*MB*) is positively associated with audit fees, consistent with the notion that firms with high *MB* values are associated with greater audit complexity or high client-specific risk. We also find that *MERGE* is positively associated with audit fees, suggesting that mergers create demand for additional audit services. Finally, there exist audit fee premiums for Big 4 client firms and cross-listed companies, which is consistent with evidence reported in Choi et al. (2008, 2009).

To focus on the permanent effect of IFRS adoption on audit fees, we have excluded the initial IFRS adoption year *t* in the main test, since the initial adoption year may experience a temporary audit fee spike. Specifically, it takes time and effort for auditors to learn about new IFRS rules, but this learning effect is likely to become insignificant after the initial year of IFRS adoption. Besides, in the initial adoption year, firms are required to apply IFRS retrospectively to one year prior to IFRS adoption for the purpose of establishing comparative financial statements (IFRS 1). If auditors are required to review the restated data, then this can also cause a temporary increase in audit costs.

To obtain further insight into the temporary transitional audit fee increase in the initial IFRS adoption year, we include in Column (2) of Table 5 the observations from the adoption year and test whether audit firms charge a significantly higher fee in the year of adoption relative to post-adoption years. Specifically, we add *ADOPT* and *ADOPT* ∗ *TREAT* to Equation (2), where *ADOPT* equals 1 if it is the IFRS (pseudo-) adoption year for the treatment (control) sample, and 0 otherwise. The *ADOPT* ∗ *TREAT* (*POST* ∗ *TREAT*) term captures the incremental audit fee increases in the adoption year (subsequent post-IFRS years) brought about by IFRS adoption in the treatment sample over and beyond the general trend in audit fees. As shown in Column (2) of Table 5, the coefficient of *ADOPT* ∗ *TREAT* (β_4) is 0.073 ($t = 4.34$), which is greater than the coefficient of *POST* ∗ *TREAT* ($\beta_2 = 0.052$; $t = 2.63$). However, as shown in the third to last row of Table 5, the difference in magnitude between β_2 and β_4 is not statistically significant ($F = 1.78$; $p = 0.18$). One possible explanation for this insignificant difference is that audit firms may have spread the temporary transitional costs incurred in the initial year of IFRS adoption to subsequent years by charging higher fees in later periods.

The results reported in Table 5, taken together, suggest that IFRS adoption increases the audit fee to a higher level both in the year of adoption and in subsequent years. Stated another way, IFRS adoption results in a positive audit fee premium. This implies that the audit fee-increasing effect of the increased complexity arising from IFRS adoption dominates the associated audit fee-decreasing effect of the improved financial reporting quality.

Tests of H2, H3, and H4

H2, H3, and H4 are concerned with whether the IFRS-related audit fee premium differs systematically, depending on the increase in audit complexity associated with IFRS adoption (H2), the improvement in reporting quality brought about by IFRS adoption (H3), and the strength of a country's legal regime (H4). To test H2 through H4, we estimate Equation (3) and report the results in Table 6.

In Columns (1) to (3) of Table 6, we measure the strength of legal regime using the natural log of the Wingate index (*WINGATE*), the change in audit complexity ($\Delta COMPLEXITY$) using the natural log of the sum of *Absence* and *Divergence*, and the change in reporting quality ($\Delta QUALITY$) using three alternative measures, that is, $\Delta GAAPQ = ln(1 + Absence)$, $(-1) * \Delta|DA1|$, and $(-1) * \Delta|DA1|$.

As shown in Columns (1) to (3) of Table 6, the coefficient of $POST * TREAT * \Delta COMPLEXITY$ is significantly positive at less than the 5 percent level across all three columns. This is consistent with H2, suggesting that the audit fee premium associated with IFRS adoption is positively associated with the increase in audit complexity brought about by IFRS adoption in a particular country. We also find that the coefficient of $POST * TREAT * \Delta QUALITY$ is significantly negative, at less than the 5 percent level, across all three columns. This result is consistent with H3 and indicates that, *ceteris paribus*, the greater the improvement in financial reporting quality brought about by IFRS adoption, the lower the audit fee premium associated with IFRS adoption.

Finally, we find mixed results with respect to the impact of legal regime on the IFRS-related audit fee premium. In Column (1) of Table 6, where $\Delta QUALITY$ is proxied by $\Delta GAAPQ = ln(1 + Absence)$, the coefficient of $POST * TREAT * WINGATE$ is negative and significant at the 10 percent level. This result indicates that the adoption of IFRS results in a smaller IFRS-related audit fee premium in countries with a strong legal regime than in countries with a weak legal regime. According to Observation 4, this result suggests that the greater audit effort induced by a stronger legal regime has a stronger effect on reducing auditors' expected legal liability cost and, hence, reducing audit fee premium, than does the direct impact of stronger legal regime on increasing audit fee premium.[16] However, in Columns (2) and (3) of Table 6, where $\Delta QUALITY$ is proxied by two alternative measures of discretionary accruals, namely $(-1) * |DA1|$ or $(-1) * |DA2|$, we find that the coefficient of $POST * TREAT * WINGATE$ is insignificant.[17]

In Columns (4) to (6) of Table 6, we repeat the analysis using alternative legal regime measures. Specifically, in lieu of *WINGATE*, we use both *LAW* and *ENFORCE* to capture

---

[16] We note that while a stronger legal regime increases the *level* of audit fees (e.g., Choi et al. 2008, 2009), the stronger legal regime does not necessarily translate to a greater *change* in audit fees. For example, Choi et al. (2008) predict and find that as a legal regime becomes stronger, the audit quality and audit fee differences between big and small auditors become smaller or insignificant. In this regard, our finding of a smaller IFRS-related audit fee premium in a stronger legal regime is consistent with their finding of a smaller Big 4 audit fee premium in a stronger legal regime.

[17] Multicollinearity could be a potential reason for the insignificant result for legal regime proxies in the alternative model specifications in Columns (2), (3), (5), (6) of Table 6 because the Variance Inflation Factors for the test variables exceed a threshold value of 10 in the regressions.

[a] The final sample consists of 2,860 firm-year observations from 11 EU countries in the treatment group and 9,052 firm-year observations from three OECD countries in the control group. The final sample includes observations in the pre-IFRS period (i.e., $t-1$), and the post-IFRS period (i.e., $[t+1, t+3]$), where t is the IFRS adoption year for the treatment sample or the assigned pseudo-adoption year for the control sample.

[b] Refer to Appendix B for variable definitions.

[c] Observations with absolute studentized residuals greater than 3 are deleted. The reported t-statistics (in parentheses) are based on standard errors clustering on the firm dimension.

differences in a country's legal environment. The results are qualitatively similar to those reported in Columns (1) to (3) of Table 6,[18] suggesting that our results are robust to the use of alternative proxies for a country's litigation environment.

VI. FURTHER ANALYSIS

Concurrent Reforms in the EU

Along with the introduction of mandatory IFRS reporting, the EU also made concurrent efforts to harmonize accounting and auditing practices and to enhance enforcement and governance mechanisms. For example, in 2003, the Committee of European Securities Regulators released its first standard (Standard No. 1) to develop and implement a common approach to the enforcement of IFRS throughout the EU. In addition, various efforts have been made to harmonize and improve EU auditing practices since 2002.[19] In the areas of company law and corporate governance, on May 25, 2003, the European Commission issued a communication to the European Parliament entitled *Modernizing Company Law and Enhancing Corporate Governance in the European Union—A Plan to Move Forward*, which sets up agendas for changes in various areas of corporate governance, such as the role of independent directors and shareholder rights. In short, the last decade has seen gradual changes in governance and enforcement mechanisms in the EU, along with implementation of IFRS reporting.

These concurrent changes pose an important challenge to our efforts to separate the audit fee effect of mandatory IFRS adoption *per se* from the effect associated with concurrent governance and enforcement reforms, as well as concurrent changes in accounting and auditing practices, which, for convenience, we refer to as *concurrent reforms*. In an attempt to isolate the IFRS adoption effect from the concurrent reform effect, we include in Equation (3) an additional variable, $POST * TREAT * REFORM$. For this additional test, we obtain information about country-level efforts on concurrent reforms from the Annual Executive Opinion Survey conducted by the Institute for Management Development. This survey is designed to quantify issues of competitiveness that are not easily measured, such as management practices, labor relations, and corruption. Among other questions, the survey asks respondents to evaluate the extent to which auditing and accounting practices are implemented in their firms adequately and the extent to which corporate boards supervise company management effectively. We then construct our measure of concurrent reform, denoted *REFORM*, by taking the arithmetic mean of (1) the change in corporate governance effectiveness, measured as the average of corporate governance effectiveness scores between 2006 and 2008 minus the score in 2004, and (2) the change in accounting and audit practices, measured as the average of the accounting and audit practices scores between 2006 and 2008 minus the score in 2005.[20]

We estimate Equation (3) with $POST * TREAT * REFORM$ being added. The untabulated results show that the coefficient of this additional variable is insignificant. More importantly, with the exception that the coefficient of $POST * TREAT * LAW$ becomes insignificant, the results for our test variables remain qualitatively similar to those reported in Table 6, suggesting that our main results are unlikely to be driven by concurrent reforms. Admittedly, our measure of concurrent reform and the difference-in-differences design may not sufficiently control for the effect of concurrent changes on our test results. As in other studies (Barth et al. 2008; Daske et al. 2008), we therefore cannot completely rule out the possibility that the audit fee-increasing effect of IFRS adoption reported in this study reflects the combined effects associated with IFRS adoption and other concurrent reforms.

---

[18] The term "qualitatively similar" or "qualitatively unchanged" in this paper means that both the signs and the statistical significance for the variables of interest remain unaltered.

[19] After the Enron scandal in the U.S., a meeting of EU Finance Ministers in May 2002 called on the Commission to adopt Recommendation 2002/590/EC, *Statutory Auditors' Independence: A Set of Fundamental Principles*. In September 2003, the Commission published *Communication on Reinforcing the Statutory Audit in the EU* (2003/236/02). In April 2006, the EU Council adopted the *Statutory Audit Directive* (2006/43/EC), also known as E-SOX, with a deadline of June 2008 for all member states to ensure that all local laws are in compliance with this directive.

[20] We use the 2005 score as an approximation for the pre-IFRS measure because the survey data related to auditing and accounting practices were not available until 2005.

Change Analyses

Our main analyses have thus far used pooled cross-sectional regressions of audit fees on our test variables, firm-specific controls, and country indicators. In an attempt to mitigate concern about potential problems of correlated omitted variables, we also conduct change analyses. We examine whether the audit fee change from the pre-IFRS to the post-IFRS periods, denoted *ΔAUDFEE,* is associated with our test variable *TREAT*, and how this association varies with *ΔCOMPLEXITY*, *ΔQUALITY*, and the strength of legal regime. For this purpose, we estimate the following regression:

$$\begin{aligned}\Delta AUDFEE = {} & \gamma_0 + \gamma_1 TREAT + \gamma_2 TREAT*\Delta COMPLEXITY + \gamma_3 TREAT*\Delta QUALITY \\ & + \gamma_4 TREAT*Legal\ Regime + \gamma_5 TREAT*REFORM + \Sigma\delta_k \Delta FSCONTROL_k + \varepsilon,\end{aligned} \tag{4}$$

where all variables are as defined earlier. In each of the post-IFRS years (t+1, t+2, t+3), we calculate $\Delta FSCONTROL_k$ relative to the pre-IFRS year (t–1). We use the same set of firm-specific controls as in Equation (3), except that we exclude *NBS*, *NGS*, *BIG4*, and *CROSS* because, as explained in footnote 12, all these variables are treated as static variables to be measured as of 2008. To address the change in the *LOSS* indicator in Equation (3), following Ghosh and Pawlewicz (2009), we create two indicator variables: (1) *Noloss-to-Loss* is an indicator variable that equals 1 for firms that report no loss in the pre-IFRS period but report a loss in the post-IFRS period, and 0 otherwise; (2) *Loss-to-Noloss* is an indicator variable that equals 1 for firms that report a loss in the pre-IFRS period but report no loss in the post-IFRS period, and 0 otherwise. For other indicator variables included in Equation (3), that is, *SPECIAL_ITEM*, *QUALIFIED*, *MERGE*, and *FINANCE*, we again create separate indicator variables in a similar manner.

Column (0) of Table 7 reports the results of our baseline change regression, in which the test variable is *TREAT*. Consistent with results in Table 5, we find that the coefficient of *TREAT* is significantly positive (0.042; t = 2.25). This leads us to reject null H1, suggesting that the audit fee increases associated with IFRS adoption are greater for adopter firms in the treatment sample than for non-adopter firms in the control sample.

Columns (1)–(6) of Table 7 report the results of the impact of the institutional factors on the IFRS-related audit fee premium across countries. Similar to our main research design using level-based analyses, in Columns (1) to (3), the strength of the legal regime is proxied by *WINGATE*, while in Columns (4) to (6), it is proxied jointly by *LAW* and *ENFORCE*. We find that, except for the insignificant coefficient of *TREAT* ∗ *LAW*, all of the results for our test variables are consistent with our main finding as reported in Tables 6. The corroborating results alleviate concerns about potential problems of correlated omitted variables.

Cross-Country Variation in Sample Size

As shown in Table 2, our sample size varies across countries. To address concerns that our results may be unduly influenced by the unequal distribution of sample firms across countries, we conduct two additional analyses. First, since U.K. firms represent a large portion of our sample, we

*, **, *** Indicate statistical significance at the 10 percent, 5 percent, and 1 percent levels, respectively, using a two-tailed test.

[a] The final sample consists of 2,027 firm-year observations from 11 EU countries in the treatment group and 6,201 firm-year observations from three OECD countries in the control group. The intercept and firm-specific control variables are not reported for parsimony, but the reported coefficients stem from estimating the full model of Equation (4).

[b] The dependent variable is the change in audit fees ($\Delta AUDFEE$). Here Δ is a change operator defined as the difference between the number in each of the post-IFRS years (t+1, t+2, t+3), and that in the pre-IFRS year (t–1). See Appendix B for variable definitions.

[c] Observations with absolute studentized residuals greater than 3 are deleted. The reported t-statistics (in parentheses) are based on standard errors clustering on the firm dimension.

repeat our main analyses after deleting the U.K. observations. Untabulated results show that all our findings remain qualitatively unchanged, except that the negative coefficient of *POST* ∗ *TREAT* ∗ *WINGATE* becomes insignificant. Our explanation is that removing the U.K. significantly reduces the cross-country variation in legal regime. Second, following Daske et al. (2008), we randomly select up to 150 firms in each country and re-estimate all the regressions. The untabulated results for our test variables using this approach remain qualitatively similar to those reported in Tables 5 to 7.

Auditor Switches

As mentioned earlier, Worldscope only provides the auditor identity data for the most recent year, 2008. One concern is that auditor switches during the sample period may confound our empirical analysis of the IFRS-related fee change, as the switch from non-Big 4 to Big 4 auditors may lead to an audit fee increase for the switching clients.

To address this potential confounding effect, we obtained the 2005 version of Worldscope that includes the auditor identity data as of 2004, the first year of our sample period. To identify auditor changes, we compare auditors as of 2004 with auditors as of 2008. Our final treatment sample consists of 833 firms, of which information on auditor change is available for 802 firms. Among these, 34 firms (4.24 percent) switched from non-Big 4 to Big 4 auditors, and 35 firms (4.36 percent) switched from Big 4 to non-Big 4 auditors. This relatively small rate of auditor switches suggests that auditor switches are unlikely to cause systematic biases to our results. Moreover, the untabulated results after excluding firms with auditor changes remain qualitatively unchanged, suggesting that the IFRS-related audit fee premium observed in our main analyses is unlikely to be driven by auditor changes that occurred during our sample period.

VII. SUMMARY AND CONCLUDING REMARKS

We investigate the impact of IFRS on audit fees using audit fee data from EU countries that mandated IFRS adoption in 2005. Our theoretical analysis suggests that IFRS adoption has two opposite effects on audit fees. On the one hand, the increase in audit task complexity arising from IFRS adoption increases audit fees, but on the other hand, the improvement in financial reporting quality leads to a decrease in audit fees. Our empirical tests show that mandatory IFRS adoption leads to an increase in audit fees, which suggests that the increase in audit task complexity is the driving force behind the IFRS-related audit fee increase. Further, we find that the IFRS-related audit fee premium increases with the extent of accounting differences between a country's former local GAAP and IFRS, and decreases with improvements in financial reporting quality brought about by IFRS adoption. We also find some evidence that the IFRS-related audit fee premium decreases with the strength of a country's legal regime.

Our study provides a theory and supporting evidence for understanding the impact of accounting standards, and their changes, on audit pricing. In particular, our results provide useful insights into the channels of audit complexity and financial reporting quality through which the adoption of new accounting standards influences audit pricing. To further understand the impact of IFRS on the auditing profession, we recommend that future research examine the audit fee effect of IFRS adoption on client companies with different characteristics, as well as how IFRS affects the interactions between real activities manipulation and accrual-based earnings management.

APPENDIX A

Proof of Observation 2

$$\Delta f \approx df = \frac{\partial f}{\partial q}\Delta q + \frac{\partial f}{\partial c}\Delta c = (1 - e^*)^2 rl[(1 - q)\Delta c - c\Delta q].$$

Thus, $df > 0$ ($df < 0$) if $(1 - q)\Delta c > c\Delta q$ (if$(1 - q)\Delta c < c\Delta q$), where Δc and Δq denote the changes in audit complexity and financial reporting quality that are brought about by IFRS adoption. ■

Proof of Observation 4

$$\begin{aligned}\frac{\partial df}{\partial r} &= \frac{\partial df}{\partial r}\Big|_{e=e^*} + \frac{\partial df}{\partial e}\frac{\partial e}{\partial r}\\ &= (1 - e)l[(1 - q)\Delta c - c\Delta q][k - (1 - q)rcl].\end{aligned}$$

Hence, given $(1 - q)\Delta c > c\Delta q$, we know from the above derivation that $\frac{\partial df}{\partial r} < 0 \left(\frac{\partial df}{\partial r} > 0\right)$ when $r > \frac{k}{cl(1-q)} \left(r < \frac{k}{cl(1-q)}\right)$. ■

APPENDIX B

EMPIRICAL DEFINITIONS OF VARIABLES

Variable		Empirical Definition	Data Source
The Dependent Variable and Country-Specific Variables			
AUDFEE	=	natural log of audit fees in thousands of euros;	Worldscope
TREAT	=	1 for firms in the treatment sample (i.e., mandatory adopter firms in EU countries) and 0 for firms in the benchmark control sample (i.e., non-adopter firms in non-EU OECD countries);	Worldscope
POST	=	1 for the post-IFRS period and 0 for the pre-IFRS period. For firms in the control sample, we assign the pseudo-adoption year 2005 (2006) for firms with a December (non-December) fiscal year-end;	Worldscope
Δ*COMPLEXITY*	=	change in audit complexity, measured by the natural log of the sum of the *Absence* score and the *Divergence* score. The *Absence* score captures the number of absent items in local GAAP compared with IFRS. The *Divergence* score captures the number of accounting rules regarding the same accounting issue that differ between IFRS and local GAAP;	Ding et al. (2007)
Δ*GAAPQ*	=	change in accounting standard quality, measured by the natural log of 1 plus the *Absence* score, where the *Absence* score captures the number of absent items in local GAAP compared to IFRS;	Ding et al. (2007)
Δ|*DA1*|	=	country's median value of the absolute value of discretionary accruals in the post-IFRS period (i.e., $[t+1, t+3]$) minus the median value in the pre-IFRS period (i.e., $t-1$), where discretionary accruals are the residuals from the cross-sectional Jones (1991) model. Refer to Appendix C for more details;	Worldscope
Δ|*DA2*|	=	country's median value of the absolute value of discretionary accruals in the post-IFRS period (i.e., $[t+1, t+3]$) minus the median value in the pre-IFRS period (i.e., $t-1$), where discretionary accruals are the residuals from the augmented cross-sectional Dechow-Dichev model. Refer to Appendix C for more details;	Worldscope
WINGATE	=	strength of a country's legal regime, measured by the natural log of the Wingate (1997) litigation index;	Wingate (1997)
LAW	=	1 for countries with a common law legal tradition and 0 for countries with a civil law tradition;	La Porta et al. (1998)
ENFORCE	=	aggregate measure of public enforcement, equal to the arithmetic mean of (1) the supervisor characteristics index, (2) the rule-making power index, (3) the investigative powers index, (4) the orders index, and (5) the criminal index; and	La Porta et al. (2006)

(continued on next page)

APPENDIX B (continued)

Variable		Empirical Definition	Data Source
REFORM	=	aggregate measure of the effect of concurrent reforms, equal to the arithmetic mean of (1) the average score of corporate board effectiveness between 2006 and 2008 minus the score in 2004 and (2) the average score of auditing and accounting practices between 2006 and 2008 minus the score in 2005.	IMD (2010) World Competitiveness Yearbook
Firm-Specific Control Variables (*FSCONTROL*)			
LNTA	=	natural log of year-end total assets in thousands of euros;	Worldscope
INVREC	=	sum of inventories and receivables divided by total assets;	Worldscope
NBS	=	natural log of 1 plus the number of business segments;	Worldscope
NGS	=	natural log of 1 plus the number of geographical segments.	Worldscope
MB	=	year-end market-to-book ratio, defined as firm market value divided by the common shareholder equity;	Worldscope
LOSS	=	1 when a firm reports a net loss, and 0 otherwise;	Worldscope
LEV	=	ratio of year-end total liabilities to total assets;	Worldscope
QUICK	=	quick ratio, equal to quick assets divided by current liabilities;	Worldscope
SPECIAL_ITEM	=	1 if the firm reports special items, and 0 otherwise;	Worldscope
QUALIFIED	=	1 if the firm receives qualified opinions, and 0 otherwise;	Worldscope
MERGE	=	1 if the firm is engaged in a merger or acquisition, and 0 otherwise;	Worldscope
FINANCE	=	1 if *MERGE* is not equal to 1 and either of the following conditions applies: long-term debt increased by 20 percent or more, or the number of shares outstanding increased by 10 percent or more after controlling for stock splits;	Worldscope
BIG4	=	1 when a firm uses one of the Big 4 auditors, and 0 otherwise; and	Worldscope
CROSS	=	1 when a firm is cross-listed in a foreign country, and 0 otherwise.	Worldscope

APPENDIX C
CONSTRUCTION OF DISCRETIONARY ACCRUALS

Following prior literature, we adopt two widely used models to estimate the normal accruals with residuals from the models as measures of discretionary accruals (denoted *DA1* and *DA2*). The first model, the cross-sectional Jones (1991) model, is specified as:

$$TA_t = \beta_0 + \beta_1 \Delta REV_t + \beta_2 PPE_t + \varepsilon_t, \tag{C1}$$

where TA_t is total accruals in year t, that is, income before extraordinary items minus operating cash flows; ΔREV_t is change in net revenues from year $t-1$ to year t; and PPE_t is net property, plant, and equipment. The second model, the augmented cross-sectional Dechow and Dichev (2002) model, follows Francis et al. (2005) and is specified as:

$$TCA_t = \beta_0 + \beta_1 CFO_{t-1} + \beta_2 CFO_t + \beta_3 CFO_{t+1} + \beta_4 \Delta REV_t + \beta_5 PPE_t + \varepsilon_t, \tag{C2}$$

where TCA_t is total current accruals in year t, calculated as ΔCA_t (change in current assets) $-$ ΔCL_t (change in current liability) $-$ $\Delta Cash_t + \Delta STDEBT_t$ (change in debt in current liabilities); CFO_t, CFO_{t-1}, and CFO_{t+1} are cash flow from operations in year t, $t-1$, and $t+1$, respectively; ΔREV_t is change in net revenues from year $t{-}1$ to year t; and PPE_t is net property, plant, and equipment. All variables are scaled by total assets at the beginning of the period, and subscripts for firm i and country j are suppressed.

Both models are estimated cross-sectionally for each industry-year within each country, with industry definition based on the Fama and French (1997) ten-industry classification. Industry-year combinations with fewer than seven observations are deleted. To run the regression, we use all observations with data available for the estimation, except firms that adopted IFRS voluntarily and those in the banking, insurance, and other financial industries. For the pre-IFRS period, the measures are based on data reported under domestic GAAP, and for the post-IFRS period the measures are based on data reported under IFRS. It would be inappropriate here to use restated financial data (following IFRS) in the pre-IFRS period, since the restated financial data would omit the change in financial reporting quality associated with different accounting systems. Note that we use semi-annual data for our analysis instead of annual data. Semi-annual data are not subject to the auditing process and, hence, better capture the pre-audit financial reporting quality in our theoretical model. Since some firms provide quarterly disclosures while others provide semi-annual disclosures, we standardize the data by aggregating quarterly data into semi-annual data.

Management Forecast Accuracy and CEO Turnover

Chul W. Park
The University of Hong Kong

ABSTRACT: We investigate whether management forecast accuracy provides a signal regarding CEOs' ability to anticipate and respond to future events by examining the relation between management forecast errors and CEO turnover. We find that the probability of CEO turnover is positively related to the magnitude of absolute forecast errors when firm performance is poor and that this positive relation holds for both positive and negative forecast errors. In addition, we find that the positive relation between CEO turnover and the absolute forecast errors is concentrated in the sample of less entrenched CEOs. Our findings indicate that boards of directors use management forecast accuracy as a signal of CEOs' managerial ability and that managers bear a cost for issuing inaccurate forecasts.

Keywords: *management forecast accuracy; CEO ability; CEO turnover.*

I. INTRODUCTION

Prior literature documents that management forecasts provide a key source of information to the capital market (Patell 1976; Ajinkya and Gift 1984; Waymire 1984; Pownell and Waymire 1989; Kasznik and Lev 1995; Frankel et al. 1995; Coller and Yohn 1997; Lennox and Park 2006). However, there is little empirical evidence regarding the role of management forecasts in the Chief Executive Officer (CEO) labor market.[1] Trueman (1986) suggests that

We appreciate the helpful comments from Clive Lennox, Shail Pandit, two anonymous reviewers, and seminar participants at the 2009 AAA Annual Meeting, Nanyang Technological University, National University of Singapore, Seoul National University, The University of Illinois at Chicago, The University of Hong Kong, and University of Oregon. [1] In contemporaneous research, Zamora (2009) documents evidence that Chief Financial Officers are rewarded for demonstrating superior forecasting ability.

management earnings forecasts provide a public signal regarding a manager's ability to anticipate future changes in the firm's business environment and to adjust the firm's operations accordingly. Given the importance of these skills to a firm's success in a competitive product market, we predict that the board of directors is more likely to replace their CEO if management forecast outcomes indicate that the CEO lacks those abilities. In this study, we provide empirical evidence as to whether boards of directors consider management forecast accuracy as a signal of the CEO's managerial ability by examining the relation between forecast accuracy and the board's decision to retain or replace the CEO.

The skills necessary to generate an accurate forecast of earnings are closely related to the skills necessary to effectively manage a firm in an uncertain environment. Managers who issue more accurate forecasts are likely to have a better understanding of how changing business conditions affect the firm's product demand and cost structure and be able to more effectively respond to future changes in the economic environment. Thus, managers who have a stronger ability to deal with uncertain future events should be able to issue more accurate forecasts of earnings. If management's earnings forecast accuracy serves as an indicator of the CEO's managerial ability, then the board of directors is likely to incorporate that information into the decision as to whether to retain or replace the CEO. Thus, we predict that the absolute management forecast error, which is inversely related to the forecast accuracy, is positively associated with the probability of CEO turnover.

While the board is likely to consider management forecast accuracy as a valuable signal of the CEO's managerial ability, the board also receives signals regarding overall firm performance. Given that the firm incurs substantial costs from replacing the CEO (e.g., severance payments and the disruption to the firm's operations), the board is more likely to replace the CEO when multiple signals are congruent. Prior literature suggests that financial performance is a strong indicator of CEOs' operating ability (e.g., Warner et al. 1988; Weisbach 1988). Thus, if firm performance is good, then the board is less likely to change leadership based solely on forecast accuracy. However, when firm performance is poor, less accurate forecasts are likely to reinforce the board's concern about the CEO's managerial ability, thereby increasing the probability of CEO turnover. As a result, we predict that the positive relation between the absolute management forecast error and CEO turnover is likely to be stronger when firm performance is poor.

Our first two predictions assume that the board is able to replace the CEO as it revises its beliefs regarding the CEO's ability. However, in some firms, CEOs wield a substantial degree of power within the corporate organization and the board may find it difficult to overcome entrenchment and replace the CEO (Dikolli et al. 2009). We therefore predict that the positive relation between the absolute management forecast error and CEO turnover is more likely to hold when the CEO is less entrenched.

We test our predictions using a sample of 30,481 firm-quarters collected from the intersection of the ExecuComp, Compustat, CRSP, First Call, and Thompson databases. Our sample period consists of quarterly observations for the period from 1996 to 2006. Since managers forecast earnings on a voluntary basis, we jointly estimate the management forecast issuance and CEO turnover decisions to control for potential selection bias in the estimation of the impact of forecast outcomes on CEO turnover.

We find a significantly positive association between the absolute management forecast error and the probability of CEO turnover. This finding is consistent with the board of directors using management forecast accuracy as a signal of the CEO's managerial ability. To gauge the economic significance of our results, we shift the absolute management forecast error from the 25th (10th) percentile to the 75th (90th) percentile and find that the likelihood of CEO turnover increases by 0.46 (1.17) percent. This change represents an increase of 16.6 (42.2) percent from the unconditional average turnover rate of 2.77 percent. The marginal effects are also relatively large compared to other indicators of the CEO's ability and performance such as return on equity, 0.15 (0.38) percent; cumulative abnormal market return, 0.41 (0.91) percent; and analyst forecast error, 0.17 (0.59) percent.

In addition, when we classify firms into a good or poor-performance group based on the signs of quarterly analyst forecast errors, we find that the positive relation between the absolute management forecast error and the probability of CEO turnover remains significant only in the poor-performance group. These findings suggest that when firm performance is poor, an inaccurate management forecast serves as a confirming signal that the CEO needs to be replaced.

To investigate the effect of CEO entrenchment, we use CEO ownership, CEO/Chairman duality, and CEO tenure as measures of entrenchment. We use the measures to construct dummy variables representing low entrenchment and interact each dummy variable with management forecast accuracy. We find a significantly positive coefficient when entrenchment is based on CEO ownership or CEO tenure. These findings are consistent with the prediction that the positive relation between the absolute management forecast error and CEO turnover is stronger when the CEO is less entrenched.

We also examine whether the relation between management forecast accuracy and CEO turnover depends on the sign of management forecast errors and find that the magnitudes of both positive and negative forecast errors are positively related to CEO turnover when firm performance is poor. The finding with positive forecast errors (i.e., reported earnings exceed the forecast) indicates that management forecast accuracy is not a proxy for overall firm performance.

Finally, to further validate our inferences, we apply our management turnover model to a holdout sample using data from 2007–2010. We find that our primary model with the management forecast error and poor performance interaction generally reduces the cost of prediction errors relative to a naive model and relative to the primary model without management forecast error terms.

Our study contributes to the literature on CEO turnover by documenting the importance of management earnings forecasts as a signal of CEOs' managerial ability in CEO replacement decisions. Prior CEO turnover literature has documented performance measures (Warner et al. 1988; Weisbach 1988; Murphy and Zimmerman 1993; Puffer and Weintrop 1991; DeFond and Park 1999; Farrell and Whidbee 2003) and governance structures (Weisbach 1988; Hermalin and Weisbach 1998; Yermack 1996; Goyal and Park 2002) as important determinants in CEO turnover decisions. Our study differs from prior literature in that if overall firm performance is poor, then we find a positive relation between CEO turnover and the absolute management forecast error even when managers beat their own forecasts. Therefore, our results suggest that management forecast accuracy is used as a distinct measure of CEO ability as opposed to an additional measure of overall firm performance.[2]

While our findings complement Zamora's (2009) evidence that strong forecasting ability increases a CFO's labor market value, our study expands the literature in several respects. First, our results suggest that even though the CEO's responsibilities are generally much broader than the CFO's financial or accounting duties, CEOs are also individually held responsible for forecast accuracy when boards deliberate on CEO dismissal. Thus, our study adds to the literature that documents CEO-specific effects on a firm's disclosure, financial reporting, and tax policies (Bamber et al. 2010; Dyreng et al. 2010) by providing evidence that firms use management forecast accuracy to assess the individual CEO's managerial ability. This evidence is consistent with Yang's (2012) evidence that the capital market incorporates the individual CEO's reputation for accuracy in assessing the information content of a management forecast. Second, despite the high costs of CEO replacement, we find that CEO turnover is negatively related to forecast accuracy. This finding suggests that forecasting accuracy is a relatively powerful signal regarding CEO ability. Third, our evidence that the relation between forecast accuracy and CEO turnover is stronger when performance is poor provides insight into how boards use forecast accuracy in conjunction with general performance measures to assess the CEO's managerial ability. Fourth, by documenting that the relation between forecast accuracy and CEO turnover is stronger when the CEO is less entrenched, our study also provides insight into how corporate governance structure affects boards' use of forecasting accuracy in evaluating the CEO. Finally, our study has implications for CEOs' expectations management strategy. If CEOs issue overly pessimistic forecasts to create positive earnings surprises on the earnings announcement date (Cotter et al. 2006), then our evidence suggests that this strategy may backfire because intentionally biasing a forecast reduces its accuracy and increases the probability of CEO turnover.

---

[2] For example, Mergenthaler et al. (2011) find that CEO turnover increases when the firm misses the consensus analyst forecast. One interpretation of their finding is that missing the analyst forecast is a measure of poor firm performance. In contrast, our results suggest that CEO turnover increases with absolute management forecast errors even when the firm does not miss the management forecast.

The rest of our paper is organized as follows. We develop our hypotheses in Section II and discuss our research design in Section III. Section IV presents the empirical results and Section V summarizes and concludes the paper.

II. HYPOTHESIS DEVELOPMENT

Prior studies document evidence that management uses voluntary disclosures to reduce information asymmetry between managers and investors (Ajinkya and Gift 1984; Ajinkya et al. 2005; Karamanou and Vafeas 2005; Lennox and Park 2006; Hui et al. 2009), manage earnings expectations (Matsumoto 2002; Cotter et al. 2006), reduce litigation costs (Skinner 1994; Kasznik and Lev 1995; Skinner 1997; Soffer et al. 2000; Field et al. 2005; Rogers and Buskirk 2009), or affect stock-based compensation (Noe 1999; Aboody and Kasznik 2000; Cheng and Lo 2006). All of these studies focus on the disclosure decision and do not recognize differences in managers' forecasting ability.

Trueman (1986) argues that managers' ability to anticipate and respond to future events is valued in the equity market and that managers can signal their ability by issuing a forecast. Trueman's (1986) model shows that a separating equilibrium exists in which only high-ability managers issue forecasts. However, in reality we would expect to observe some low-ability managers issuing forecasts, either because they have overconfidence in their own ability, or they want to mimic managers of high ability. In this case, we expect the accuracy of management's forecast to reflect the CEO's ability. Forecasts are likely to be more accurate when the manager has the ability to develop and maintain a high-quality accounting information system that provides reliable data, and has the ability to accurately anticipate changes in business environment and their impact on earnings. Thus, we expect management forecast accuracy to serve as an observable measure of the CEO's managerial ability to adapt to a changing economic environment.

The evidence documented by Zamora (2009) supports this theory by showing that forecasting ability is associated with a CFO's labor market value. Specifically, Zamora (2009) finds that CFOs who show superior forecasting ability are more likely to have a higher reservation wage or to take a career-advancing opportunity such as an internal promotion or a move to another firm at an equal or higher position. Since CFOs are generally focused on financial management, including communications with capital market participants, the ability to forecast earnings is directly related to the CFO's primary job responsibilities. In contrast, financial management is just one aspect of the CEO's broader set of responsibilities. Thus, it is an empirical question as to whether boards consider management forecast accuracy as an indicator of the CEO's managerial ability and incorporate forecast accuracy in the CEO turnover decision.

If management forecast accuracy signals a CEO's ability to manage the firm, then the board of directors is likely to hold the CEO responsible for the accuracy and likely to incorporate that information into their decision to replace or retain the CEO. Specifically, boards are more likely to retain CEOs who issue accurate forecasts and more likely to replace CEOs who issue inaccurate forecasts. Since management earning forecast accuracy is inversely related to the absolute value of the forecast error, our first hypothesis (stated in alternative form) is:

> **H1:** *Ceteris paribus*, the probability of CEO turnover is positively related to the absolute management forecast error.

H1 predicts that boards are likely to penalize CEOs for issuing inaccurate forecasts. However, prior literature suggests that boards provide CEOs with incentives to issue pessimistic forecasts in order to generate beatable earnings targets (Richardson et al. 2004; Cotter et al. 2006) or with incentives to issue optimistic forecasts to increase analyst coverage or favorable press coverage (McNichols and O'Brien 1997). The extent to which boards reward CEOs who intentionally issue inaccurate forecasts would reduce the power of our tests.

While management forecast accuracy is likely to signal the CEO's managerial ability, the costs associated with removing a CEO, including contractual severance payments and costs from the disruption to the firm's operations, are high and management forecast accuracy is likely to be evaluated in conjunction with the firm's overall performance. If the firm's overall performance is good, then the board is unlikely to change the leadership of the firm and incur the associated costs even if the management forecast is inaccurate. On the other hand, if firm performance is poor, then the board is likely to consider management forecast accuracy as an additional signal to confirm that the poor performance is attributable to the CEO's poor managerial ability. Specifically, when performance is poor, an accurate management earnings forecast is likely to temper the board's concerns regarding the CEO's ability, whereas an inaccurate forecast is likely to reinforce the board's concerns.

Based on the above discussion, we form the second hypothesis:

> **H2:** *Ceteris paribus*, the positive relation between the probability of CEO turnover and the absolute management forecast error is stronger when firm performance is poor than when firm performance is good.

The first two hypotheses assume that boards of directors choose to retain or remove CEOs based on signals regarding the ability of the CEO. However, CEO entrenchment may make it difficult for the board to replace a CEO of poor ability. Specifically, the board may not be able to remove an entrenched CEO who holds relatively large blocks of voting stock or has the power to influence the selection of outside board members, even if the board observes negative signals of the CEO's ability. In contrast, when CEOs are less entrenched, boards are more likely to replace CEOs who are deemed to have poor managerial ability. As a result, we expect less entrenched CEOs to be more vulnerable to dismissal when their forecasts are inaccurate. Thus, our third hypothesis is:

> **H3:** *Ceteris paribus*, the positive relation between the probability of CEO turnover and the absolute management forecast error is more likely to hold when the CEO is less entrenched.

III. RESEARCH DESIGN

Sample Selection and Descriptive Data

We draw our sample from the intersection of the ExecuComp, First Call, Compustat, CRSP, and Thompson databases for the years 1996 to 2006. We use the ExecuComp database to identify CEOs and CEO turnover. We collect management earnings forecasts from the First Call database. Each sample observation must have accounting and stock market data in the Compustat and CRSP databases and institutional ownership data in the Thompson database.

Analyst Forecast for t-1
Disclosure Quarter (Management Forecast for t-1)
Turnover Quarter

This figure illustrates the sequence of events for our study. For each potential turnover quarter *t*, we examine the management forecast for quarter *t*–1 (disclosure quarter). We include a management forecast for quarter *t*–1 in the disclosure decision analysis if the firm issued the forecast during the period from the beginning of quarter *t*–1 to the end of quarter *t*–1. We measure forecast accuracy by the absolute value of the management forecast error that is measured by actual EPS minus the first management forecast EPS in quarter *t*–1, scaled by price at the beginning of the quarter *t*–1.

These procedures yield 30,481 firm-quarter observations, of which 843 (2.8 percent) have CEO turnover.[3]

Figure 1 illustrates a timeline for a firm that chooses to retain or replace the CEO during the first quarter of 2007. We label the first quarter of 2007 as potential "turnover quarter" (quarter *t*) and label the fourth quarter of 2006 as the "disclosure quarter" (quarter *t*–1) during which the manager chooses to issue a forecast for that quarter. We exclude management forecasts that are issued after the end of the fiscal quarter because they often represent preliminary earnings announcements rather than earnings forecasts (e.g., Skinner 1997; Rogers and Stocken 2005). A management earnings forecast can take a form of point, range, or open-ended forecast. We do not include open-ended forecasts because their forecast errors are not well defined. Our sample includes 5,312 (76 percent) range forecasts and 1,636 (24 percent) point forecasts.[4] Among the forecast observations, 18.4 percent issue multiple earnings forecasts in the form of point or range during the quarter. We choose the first forecast if managers issue the multiple forecasts. Our results remain qualitatively unchanged when we choose the last forecast.

We assume that when the board makes a decision on CEO turnover in quarter *t*, the board considers the accuracy of the management earnings forecast for quarter *t*–1 that is issued during quarter $t-1$.[5] This assumption allows us to link the turnover action in quarter t directly to the management forecast error in quarter $t-1$. However, this design assumes a relatively quick reaction by the board to the management forecast signal. To allow for the possibility of the board's delayed reaction to the forecast error, we extend the turnover window to encompass two quarters, quarter t and quarter $t+1$. We find qualitatively similar results. Alternatively, we relax the restriction of relying on the management forecast error of quarter $t-1$ and use the average management forecast error over quarters $t-4$ to $t-1$.[6] The results are robust to this change.

---

[3] The quarterly turnover rate of 2.8 percent is similar to the 3 percent rate in Dikolli et al. (2009) and corresponds to an annual rate of approximately 11.2 percent, which is consistent with the rates documented in prior CEO turnover studies such as Goyal and Park (2002).

[4] In a supplemental untabulated test we compare results for point forecasts to the results for range forecasts and do not find a significant difference.

We measure management earnings forecast accuracy using the absolute value of the forecast error. The smaller the absolute forecast error, the more accurate the forecast. We define the management forecast error for the disclosure quarter $t-1$ as the difference between actual earnings per share for quarter $t-1$ and the management earnings forecast for the quarter, scaled by the share price at the beginning of quarter $t-1$.

Panel A of Table 1 presents the CEO turnover rates based on the management forecast error. We observed a management forecast in 6,948 (22.8 percent) of the 30,481 firms-quarters. For the 23,533 quarters without a management forecast, the unconditional turnover rate of 2.72 percent is close to the overall average of 2.77 percent. When we partition the sample into quintile groups based on the magnitude of the forecast error, we find that the turnover rate is greater for firms in the lowest forecast error quintile (actual earnings are below the forecast) and for firms in the highest forecast error quintile (actual earnings are above the forecast). This is consistent with the prediction that CEO turnover rates are negatively related to management earnings forecast accuracy.

We then split the sample based on firm performance in quarter $t-1$ (the disclosure quarter). As shown in Figure 1, to measure firm performance we use the most recent analyst forecast for quarter $t-1$ issued prior to the earnings announcement date for quarter $t-2$ and define analyst forecast error as the difference between the actual earnings for quarter $t-1$ and the analyst forecast.[7]

Panel B of Table 1 presents the turnover rates for firms missing the analyst forecast (i.e., poor-performance firms) and Panel C of Table 1 presents the turnover rates for firms meeting or beating the analyst forecast (i.e., good-performance firms). Consistent with the findings of Dikolli et al. (2009), the turnover frequencies for poor-performance firms are higher than those for good-performance firms. We also note that for good-performance firms (Panel C) the turnover rates for each quintile group are generally close to the turnover rates for firms that do not issue management forecasts. In addition, we find that the differences between the turnover rate for the most accurate management forecast quintile (Quintile 3) and the extreme management forecast error quintiles (Quintiles 1 and 5) groups are larger for poor-performance firms than for good-performance firms. This result is consistent with the prediction that management forecast accuracy is a more useful signal regarding a CEO's managerial ability when firm performance is poor than when firm performance is good.

---

[5] We assume that the board is aware of the actual earnings for quarter $t-1$ at the time they make the CEO retention decision. Although the public earnings announcement is likely to occur 10 to 45 days after the end of quarter $t-1$, the board is likely to have preliminary numbers before they are released to the public.

[6] We find that the correlation between the management forecast error over quarters $t-4$ to $t-2$ and quarter $t-1$ is 0.421. The persistence of forecast accuracy is consistent with CEOs with higher forecasting talent consistently producing more accurate forecasts.

[7] There is the possibility that our measure of firm performance, analyst forecast error, is contaminated by the management forecast. To address this issue, we conduct several sensitivity checks. First, we drop 254 observations where the management forecast is issued before the prior earnings announcement date. Second, we drop 178 observations where the management forecast is issued before the analyst forecast. Third, we use the market return or the earnings change measured over the prior 12 months as alternative performance measures. The results are robust to each of these sensitivity checks.

TABLE 1

Turnover Rates and Management Forecast Outcomes

Panel A: Turnover Frequencies and Management Forecast Error

	Lowest MFE Quintile 1	Quintile 2	Most Accurate Quintile 3	Quintile 4	Highest MFE Quintile 5	No Forecast	Total
TURN = 1	49	41	37	34	42	640	843
TURN = 0	1,340	1,349	1,524	1,185	1,347	22,893	29,638
Total	1,389	1,390	1,561	1,219	1,389	23,533	30,481
Turnover Ratio	3.53%	2.95%	2.37%	2.79%	3.02%	2.72%	2.77%

Panel B: Turnover Frequencies for Poor Performance

	Lowest MFE Quintile 1	Quintile 2	Most Accurate Quintile 3	Quintile 4	Highest MFE Quintile 5	No Forecast	Total
TURN = 1	29	20	23	14	22	310	418
TURN = 0	543	552	720	387	550	9,592	12,344
Total	572	572	743	401	572	9,902	12,762
Turnover Ratio	5.07%	3.50%	3.10%	3.49%	3.85%	3.13%	3.28%

Panel C: Turnover Frequencies for Good Performance

	Lowest MFE Quintile 1	Quintile 2	Most Accurate Quintile 3	Quintile 4	Highest MFE Quintile 5	No Forecast	Total
TURN = 1	20	21	14	20	20	330	425
TURN = 0	797	797	804	798	797	13,301	17,294
Total	817	818	818	818	817	13,631	17,719
Turnover Ratio	2.45%	2.57%	1.71%	2.44%	2.45%	2.42%	2.40%

This table provides data on the unconditional quarterly CEO turnover rates based on the quintiles of management forecast errors. The lowest quintile indicates that actual earnings for the quarter are less than management forecasts. The highest quintile indicates that actual earnings for the quarter are greater than management forecasts. The middle quintile indicates the most accurate management forecast group. A timeline for the measurement of management forecasts is illustrated in Figure 1. *TURN* is 1 if the CEO leaves the firm during the turnover quarter, and 0 otherwise. The classification of good or poor performance is based on the analyst forecast error that is measured as the difference between actual earnings per share and the most recent analyst forecast of earnings per share for the disclosure quarter issued prior to the earnings announcement date for the prior quarter. Performance is good (poor) if actual earnings meet or beat (miss) analyst earnings forecasts.

Research Design

The impact of forecast outcomes on CEO turnover is conditional on management's decision to forecast earnings. Thus, we incorporate the forecast decision into our research design to control for a potential selection bias. Specifically, we follow Pandit et al. (2012) and estimate a seemingly unrelated bivariate probit with a stacked model.[8] In this design, we model both the management forecast and turnover decisions, include the disclosure dependent variable from the first model as an independent variable in the second model, and jointly estimate the two regressions. This procedure adjusts for the endogeneity of the forecast issuance decision and for the fact that forecast errors are conditional on the issuance of a forecast. Because the dependent variable of the forecast decision model is an independent variable in the turnover decision, it may be more appropriate to use a recursive simultaneous equations model. However, Greene (2000, 852–853; Greene 2002, 32, see E17) indicates that the recursive simultaneous equations model can be estimated using the seemingly unrelated bivariate probit model because their likelihood functions are identical (Maddala 1983, 123).[9]

Our empirical model for the issuance of a management forecast is based on Lennox and Park (2006) who focus on management's incentive to issue forecasts to reduce information asymmetry. We augment their model by adding controls for CEO tenure, corporate governance, and ownership structure. Specifically, we estimate the following regression:

$$\begin{aligned} MF_{it-1} = {} & \alpha_0 + \alpha_1 Prev\_Forecast_{it-1} + \alpha_2 Abs\_CXR_{it-1} + \alpha_3 LnMV_{it-1} + \alpha_4 Num\_Analysts_{it-1} \\ & + \alpha_5 MB_{it-1} + \alpha_6 Earn\_Vol_{it-1} + \alpha_7 Ret\_Vol_{it-1} + \alpha_8 High\_Tech_{it-1} + \alpha_9 REG_{it-1} \\ & + \alpha_{10} Tenure_{it-1} + \alpha_{11} Inst\_Own_{it-1} + \alpha_{12} CEO\_Own_{it-1} + \alpha_{13} Chair\_Dual_{it-1} + e_1, \end{aligned} \tag{1}$$

where:

MF = 1 if the firm issues an earnings forecast during quarter *t*–1, and 0 otherwise;
Prev_Forecast = number of quarters for which the firm issued a forecast over quarters *t*–4 through *t*–2;
Abs_CXR = absolute value of cumulative market adjusted stock returns over the 62-day window that ends on the day after the earnings announcement for quarter *t*–1;
LnMV = natural log of the market value of common equity at the beginning of quarter *t*–1;
Num_Analysts = number of analysts following the firm prior to the earnings announcement date for quarter *t*–1;
MB = market-to-book value of common equity at the beginning of quarter *t*–1;
Earn_Vol = variance of changes in quarterly earnings per share (EPS), scaled by assets per share at the beginning of quarter *t*–1. We measure the change in quarterly EPS as the quarter *t*–1 EPS minus the EPS of the same quarter for the prior year, and use the 16 most recent quarters that have data for earnings changes;
Ret_Vol = variance in daily raw stock returns over the 250 trading days prior to the beginning of quarter *t*–1. We require a minimum of 100 daily stock return observations to compute the variance;
High_Tech = 1 if the firm reports Compustat SIC codes 2833–2836 (Drugs), 8731–8734 (R&D services), 7371–7379 (Programming), 3570–3577 (Computers), or 3600–3674 (Electronics), and 0 otherwise;

---

[8] Pandit et al. (2012) examine the relation between analyst cash flow forecasts and analyst turnover. In the stacked model we adopt, when the dummy variable for the issuance of a management forecast (*MF*) has the value of 1, the turnover equation includes management forecast outcomes and our other independent variables. In contrast, when *MF* is equal to 0, the turnover equation does not include management forecast outcomes. A Heckman-style selection model is not appropriate because it assumes that turnover in the second stage is observed only for the selected case in which *MF* is equal to 1.

[9] Greene (2000) points out that simultaneity can be ignored in a bivariate probit regression. In our setting his point means that we can ignore the endogenous nature of the management forecast variable in formulating the log-likelihood of the turnover equation.

REG = 1 if the firm reports Compustat SIC codes 4812–4813 (Telephone), 4833 (TV), 4841 (Cable), 4811–4899 (Communications), 4922–4924 (Gas), 4931 (Electricity), 4941 (Water), or 6021–6023, 6035–6036, 6141, 6311, 6321, 6331 (Financial firms), and 0 otherwise;

Tenure = number of years that the CEO has held the position of chief executive officer as of the beginning of the fiscal year containing quarter *t*–1;

Inst_Own = percentage of outstanding shares owned by institutions at the beginning of quarter *t*–1; if missing, we assume institutional ownership is not reported because of minimal institutional holdings, and we set it to 0;

CEO_Own = ownership of the CEO as of the beginning of the fiscal year containing quarter *t*–1; if missing, we assume CEO ownership is not reported because of minimal CEO holdings, and we set it to 0; and

Chair_Dual = 1 if the CEO has the dual positions of chairman at the beginning of the fiscal year containing quarter *t*–1, and 0 otherwise.

This first-stage regression serves as an empirical model of the probability that firm *i* issues a forecast for quarter *t*–1 during quarter *t*–1. We include the *Prev_Forecast* variable to control for the firm's overall disclosure policy. We expect managers who have issued forecasts in the past to be more likely to issue a forecast in the current quarter. Thus, we predict the coefficient on *Prev_Forecast* to be positive.

Prior research finds that the management forecast decision is associated with the magnitude of earnings surprises and future earnings revisions, earnings informativeness, information environment, demand for information, risk, litigation, corporate governance, and ownership structure (Kasznik and Lev 1995; Frankel et al. 1995; Skinner 1994; Lennox and Park 2006; Ajinkya et al. 2005; Karamanou and Vafeas 2005). We include *Abs_CXR* to simultaneously control for earnings surprises and revisions in future earnings forecasts, and earnings informativeness.[10] We include *LnMV* to control for the information environment, *Num_Analysts*, *MB*, and *REG* to control for the information demand, *Earn_Vol* and *Ret_Vol* to control for risk, and *High_Tech* to control for litigation. Additionally, we include *Tenure* and *Chair_Dual* to capture the CEO's power in the governance structure, *Inst_Own* to measure the extent of external monitoring, and *CEO_Own* to control for management's incentives to disclose information (Ali et al. 2007; Chen et al. 2008).[11]

The second-stage regression models CEO turnover as follows:

$$\begin{aligned} Turnover_{it} = {} & \beta_0 + \beta_1 Abs(MFE)_{it-1}{*}MF_{it-1} + \beta_2 MF_{it-1} + \beta_3 AFE_{it-1} + \beta_4 ROE_{it-1} \\ & + \beta_5 CAR_{it-1} + \beta_6 Earn\_Vol_{it-1} + \beta_7 Ret\_Vol_{it-1} + \beta_8 LnSALES_{it-1} + \beta_9 AGE_{it-1} \\ & + \beta_{10} AGE65_{it-1} + \beta_{11} Tenure_{it-1} + \beta_{12} Inst\_Own_{it-1} + \beta_{13} CEO\_Own_{it-1} \\ & + \beta_{14} Chair\_Dual_{it-1} + e_2, \end{aligned} \tag{2}$$

where:

Turnover = 1 if the CEO leaves the firm during quarter *t*, and 0 otherwise;

---

[10] A control for earnings informativeness measured by the earnings response coefficient requires extensive time-series of earnings data and drastically reduces the sample observations available for our tests. Thus, we choose *Abs_CXR* as a composite measure of earnings surprises, revisions in future earnings forecasts, and earnings informativeness by relying on the prior capital market literature that documents that a firm's abnormal stock returns are a function of those three variables (e.g., Collins and Kothari 1989; Cornell and Landsman 1989).

[11] The results are qualitatively similar when we include the G-index (Gompers et al. 2003) in the management forecast and CEO turnover equations as an additional measure of corporate governance quality.

Abs(*MFE*) = absolute value of the management forecast error that is measured as actual earnings per share minus the first management forecast of earnings per share during the disclosure quarter (quarter *t*–1), scaled by the share price at the beginning of quarter *t*–1;[12]

MF = 1 if the firm issued an earnings forecast for quarter *t*–1, and 0 otherwise,

AFE = analyst forecast error that is measured as the difference between actual earnings per share for quarter *t*–1 and the most recent analyst forecast of earnings per share for quarter *t*–1 issued prior to the earnings announcement date for quarter *t*–2, scaled by the share price at the beginning of quarter *t*–1;

ROE = firm's ROE minus industry ROE over the four quarters prior to quarter *t*. The firm's ROE is calculated as the sum of earnings for quarters *t*–5 through *t*–1, scaled by common equity at the beginning of quarter *t*–4. Industry ROE is calculated as the median ROE of firms in the same industry (based on two-digit SIC codes) for the same period;

CAR = the cumulative market-adjusted stock returns over 12 months prior to the turnover quarter;

LnSALES = natural log of the sum of sales for quarters *t*–5 through *t*–1;

AGE = age of the CEO at the beginning of the fiscal year including quarter *t*; and

AGE65 = 1 if the age of the CEO = 64, 65, or 66, and 0 otherwise.

All other variables are as previously defined in Equation (1).

H1 states that the probability of CEO turnover is positively related to the absolute management forecast error and predicts that β_1, the coefficient for $Abs(MFE) * MF$, is positive. We include *MF*, the dependent variable in the first-stage regression, as a control variable in the second stage to adjust for the endogenous decision to issue a forecast and for the fact that the test variable is only observed when the firm issues a forecast.

We use analyst forecast errors, industry-adjusted earnings, and market-adjusted returns to control for firm performance and *Earn_Vol* and *Ret_Vol* to control for risk (Coughlan and Schmidt 1985; Warner et al. 1988; Murphy and Zimmerman 1993; DeFond and Park 1999; Engel et al. 2003; Farrell and Whidbee 2003). We also include CEO age and tenure as control variables along with a dummy variable indicating whether CEO age is 64, 65 or 66 to capture normal retirement ages near 65 (Weisbach 1988; Murphy and Zimmerman 1993; DeFond and Park 1999).[13] The log of sales is included to control for firm size (Farrell and Whidbee 2003). Finally, we include *Tenure*, *Chair_Dual*, and *CEO_Own* to control for CEO power, and *Inst_Own* to control for the strength of external monitoring. To reduce the influence of extreme observations we winsorize each continuous variable at the 1 percent and 99 percent values of its distribution. We cluster the standard errors by firm to reduce the potential understatement of standard errors that could result from the use of multiple observations for the same firm.[14]

Given that we use a simultaneous equations system, the identification of Equation (2) requires that the number of exogenous variables excluded from Equation (2) must be at least as large as the number of endogenous variables included in Equation (2) (Greene 2000, 670). Equation (2) has two endogenous variables, *MF* and $Abs(MFE) * MF$, and Equation (1) has seven exogenous variables that are excluded from Equation (2).[15] Thus, Equation (2) is identified. In our stacked bivariate system, Equation (1) explicitly models the decision to issue a forecast. If management believes that an inaccurate forecast will increase the probability of turnover, then it is important to incorporate the expected accuracy of forecasts in the decision model. Earnings are more likely to be difficult to predict as earnings or stock returns are more volatile. We therefore consider the risk variables, *Earn_Vol* and *Ret_Vol*, as proxies for the expected forecast error.[16]

---

[12] As a sensitivity check we also deflate by total assets per share instead of share price. The results are qualitatively similar.

[13] The reasons for CEO changes stated in press releases are often not reliable. Thus, consistent with prior studies (Weisbach 1988; Murphy and Zimmerman 1993; DeFond and Park 1999), we include all turnover firms in our test. While the inclusion of routine CEO turnover reduces the power of tests, the use of age and age dummy variables mitigate this concern. We also conduct our regressions dropping all CEOs aged 63 or older from the sample. Our results are robust.

[14] This procedure controls for serial correlation in all our analyses. Correcting cross-sectional correlation provides qualitatively the same results.

To test H2, we expand the CEO turnover regression by adding a variable that interacts a dummy variable for poor performance (*Dummy_Poor*) with *Abs*(*MFE*). We also include *Dummy_Poor* to control for its main effect on CEO turnover. Specifically, we estimate the following second-stage regression:

$$\begin{aligned} Turnover_{it} = {} & \beta_0 + \beta_1 Abs(MFE)_{it-1}{*}MF_{it-1} + \beta_2 Abs(MFE)_{it-1}{*}MF_{it-1}{*}Dummy\_Poor_{it-1} \\ & + \beta_3 MF_{it-1} + \beta_4 Dummy\_Poor_{it-1} + \beta_5 AFE_{it-1} + \beta_6 ROE_{it-1} + \beta_7 CAR_{it-1} \\ & + \beta_8 EarnVol_{it-1} + \beta_9 Ret\_Vol_{it-1} + \beta_{10} LnSALES_{it-1} + \beta_{11} AGE_{it-1} \\ & + \beta_{12} AGE65_{it-1} + \beta_{13} Tenure_{it-1} + \beta_{14} Inst\_Own_{it-1} + \beta_{15} CEO\_Own_{it-1} \\ & + \beta_{16} Chair\_Dual_{it-1} + e_3, \end{aligned} \tag{3}$$

where:

Dummy_Poor = 1 if AFE_{it-1} is negative (i.e., the firm reports earnings for quarter *t*–1 below the analyst forecast), and 0 otherwise.

All the other variables are defined as in Equations (1) and (2).

H2 states that the positive relation between the probability of CEO turnover and the absolute management forecast error is stronger when firm performance is poor than when firm performance is good. In Equation (3), β_2, the coefficient on the interaction of the absolute management forecast error with poor performance, captures the *incremental* effect of management forecast accuracy on CEO turnover for poor performing firms relative to good performing firms. We also report the *full* effect of management forecast accuracy on CEO turnover for poorly performing firms by adding β_1 and β_2. We expect both β_2 and $\beta_1 + \beta_2$ to be positive.

H3 states that the positive relation between the probability of CEO turnover and the absolute management forecast error is more likely to hold when the CEO is less entrenched. To test H3, we use CEO ownership percentage, CEO/Chairman duality, and CEO tenure to measure CEO entrenchment. Using each measure of CEO entrenchment, we estimate the following second-stage regression separately:

$$\begin{aligned} Turnover_{it} = {} & \gamma_0 + \gamma_1 Abs(MFE)_{it-1}{*}MF_{it-1} + \gamma_2 Abs(MFE)_{it-1}{*}MF_{it-1}{*}Less\_Entrenchment_{it-1} \\ & + \gamma_3 MF_{it-1} + \gamma_4 Less\_Entrenchment_{it-1} + \gamma_5 AFE_{it-1} + \gamma_6 ROE_{it-1} + \gamma_7 CAR_{it-1} \\ & + \gamma_8 Earn\_Vol_{it-1} + \gamma_9 Ret\_Vol_{it-1} + \gamma_{10} LnSALES_{it-1} + \gamma_{11} AGE_{it-1} \\ & + \gamma_{12} AGE65_{it-1} + \gamma_{13} Tenure_{it-1} + \gamma_{14} Inst\_Own_{it-1} + \gamma_{15} CEO\_Own_{it-1} \\ & + \gamma_{16} Chair\_Dual_{it-1} + e_4, \end{aligned} \tag{4}$$

where:

---

[15] The seven variables are *Prev_Forecast*, *Abs_CXR*, *LnMV*, *Num_Analysts*, *MB*, *High_Tech*, and *REG*. We find that none of the correlations between *Prev_Forecast* (*REG*) and the other exogenous variables in Equations (1) and (2) exceeds 0.18 (0.15) in absolute value. Thus, at minimum, the *Prev_Forecast* and *REG* variables that are in Equation (1) but excluded from Equation (2) are likely to serve as relatively efficient instruments for estimating the turnover equation.

[16] The pairwise correlations between each of the expected forecast error proxies and *ex post* forecast error are significantly positive. Given the high correlation (0.421) between management forecast error over quarters *t*–4 to *t*–2 and quarter *t*–1, we include the previous forecast accuracy over quarters *t*–4 to *t*–2 as an alternative proxy for expected accuracy. The results are robust to this sensitivity test.

Less_Entrenchment = 1 if CEO is less entrenched (i.e., CEO ownership percentage falls within the sample bottom quartile, or the CEO does not have the dual title, or CEO tenure falls within the sample bottom quartile), and 0 otherwise.[17]

All the other variables are defined as in Equations (1) and (2).

H3 predicts that both γ_2 and $\gamma_1 + \gamma_2$ in Equation (4) are significantly positive.

IV. EMPIRICAL RESULTS

Main Tests

Table 2 provides data on the distributions of the variables used in our empirical tests. Panel A of Table 2 includes the variables for the management forecast issuance model and Panel B of Table 2 includes the additional variables for the CEO turnover model. The mean value for *MF* of 0.228 indicates that sample firms issue a forecast in 22.8 percent of the quarters. Approximately 68.6 percent of our sample quarters includes a forecast for at least one of the previous three quarters. Among other variables, we note that the mean (median) tenure for CEOs in our sample is 8.3 (6.0) years, and the average age of the CEOs is approximately 55.5 years.

We present the results from the joint estimation of the bivariate probit regressions in Table 3. The results from the management forecast issuance model are generally consistent with our predictions. The significantly positive coefficient for *Prev_Forecast* indicates that firms are more likely to issue a forecast for a given quarter if they had issued forecasts in the prior quarters. As expected, firms that have a greater analyst following and higher institutional ownership are more likely to issue a forecast. This result is consistent with firms providing forecasts to fulfill a greater demand for information.

We use the second-stage turnover regressions (i.e., Equations (2), (3) and (4)) to test our hypotheses. The results in Table 3 support H1, which predicts that the probability of CEO turnover is positively related to the absolute value of management's forecast errors. The coefficient on the absolute management forecast error is significantly positive at the 1 percent level. This result is consistent with the board using management forecast errors as a signal of the CEO's ability to anticipate and adapt to changes in the business environment. The result also suggests that the labor market penalizes managers who issue inaccurate forecasts. The insignificant coefficient for *MF* indicates that the issuance of a forecast, in itself, does not have a significant effect on CEO turnover.[18] We also note that the coefficient for each of our measures of firm performance is significantly negative, consistent with prior studies that document an inverse relation between CEO turnover and firm performance (Coughlan and Schmidt 1985; Weisbach 1988; Puffer and Weintrop 1991; DeFond and Park 1999).

H2 predicts that the positive relation between CEO turnover and the absolute management forecast error is more pronounced when firm performance is poor. Table 4 presents the results from the management forecast issuance model and two CEO turnover regression models. The first CEO turnover model includes a dummy variable for negative analyst forecast error (*Dummy_Poor*) and excludes the continuous analyst forecast error. The second CEO turnover model includes both the negative forecast error dummy and continuous forecast error (*AFE*). In each model, the coefficient for $Abs(MFE) * MF$ is not significant but the coefficient for the interaction of $Abs(MFE) * MF$ and *Dummy_Poor*, which captures the incremental effect, is significantly positive at the 5 percent level.

---

[17] When we use CEO ownership percentage (tenure) as an entrenchment variable, we do not include *CEO_Own* (*Tenure*) in the regression.

[18] We conduct a self-selection bias test with Equations (1) and (2) and find that the bias is not significant (Chi-square = 0.619, p = 0.431). This result is consistent with the insignificant coefficient for *MF*.

Variable Definitions:

MF = 1 if the firm issues an earnings forecast during quarter *t*–1, and 0 otherwise;

Prev_Forecast = number of quarters for which the firm issued a forecast over quarters *t*–4 through *t*–2;

Abs_CXR = absolute value of cumulative market-adjusted stock returns over the 62-day window that ends on the day following the earnings announcement for quarter *t*–1;

MV = market value of common equity at the beginning of quarter *t*–1;

LnMV = natural log of *MV*;

Num_Analysts = number of analysts following the firm prior to the earnings announcement date for quarter *t*–1;

MB = market-to-book value of common equity at the beginning of quarter *t*–1;

Earn_Vol = variance of changes in quarterly earnings per share (EPS), scaled by assets per share at the beginning of quarter *t*–1. We measure the change in quarterly EPS as the quarter *t*–1 EPS minus the EPS of the same quarter for the prior year, and use the 16 most recent quarters that have data for earnings changes;

Ret_Vol = variance in daily raw stock returns over the 250 trading days prior to the beginning of quarter *t*–1. We require a minimum of 100 daily stock return observations to compute the variance;

High_Tech = 1 if the firm reports Compustat SIC codes 2833–2836 (Drugs), 8731–8734 (R&D services), 7371–7379 (Programming), 3570–3577 (Computers), or 3600–3674 (Electronics), and 0 otherwise;

REG = 1 if the firm reports Compustat SIC codes 4812–4813 (Telephone), 4833 (TV), 4841 (Cable), 4811–4899 (Communications), 4922–4924 (Gas), 4931 (Electricity), 4941 (Water), or 6021–6023, 6035–6036, 6141, 6311, 6321, 6331 (Financial Firms), and 0 otherwise;

Tenure = number of years that the CEO has held the position of chief executive officer as of the beginning of the fiscal year containing quarter *t*–1;

(continued on next page)

TABLE 2 (continued)

Inst_Own = percentage of outstanding shares owned by institutions at the beginning of quarter *t*–1; if missing, we assume institutional ownership is not reported because of minimal institutional holdings, and we set it to 0;
CEO_Own = ownership of the CEO as of the beginning of the fiscal year containing quarter *t*–1; if missing, we assume CEO ownership is not reported because of minimal CEO holdings, and we set it to 0;
Chair_Dual = 1 if the CEO has the dual positions of chairman at the beginning of the fiscal year containing quarter *t*–1, and 0 otherwise;
Turnover = 1 if the CEO leaves the firm during quarter *t*, and 0 otherwise;
Abs(*MFE*) = absolute value of the management forecast error that is measured as actual earnings per share minus the first management forecast of earnings per share during the disclosure quarter (quarter *t*–1), scaled by the share price at the beginning of quarter *t*–1;
AFE = analyst forecast error that is measured as the difference between actual earnings per share for quarter *t*–1 and the most recent analyst forecast of earnings per share for quarter *t*–1 issued prior to the earnings announcement date for quarter *t*–2, scaled by the share price at the beginning of quarter *t*–1;
ROE = firm's ROE minus industry ROE over the four quarters prior to quarter *t*. The firm's ROE is calculated as the sum of earnings for quarter *t*–5 through *t*–1, scaled by common equity at the beginning of quarter *t*–4. Industry ROE is calculated as the median ROE of firms in the same industry (based on two-digit SIC code) for the same period;
CAR = cumulative market-adjusted stock returns over 12 months prior to the turnover quarter;
SALES = sum of sales for quarter *t*–5 through *t*–1;
LnSALES = natural log of *SALES*;
AGE = age of the CEO at the beginning of the fiscal year including quarter *t*;
AGE65 = 1 if the age of the CEO = 64, 65, or 66, and 0 otherwise; and
All other variables are as previously defined.

In addition, the sum of the coefficient for *Abs*(*MFE*) and the coefficient for the interaction variable, which captures the full effect, is also significantly positive at the 1 percent level.[19] These results indicate that the management forecast accuracy is most relevant to boards' decisions on CEO turnover when overall firm performance is poor and suggest that the forecast accuracy is used as a confirming signal that the firm's poor performance is attributable to the ability of the CEO.[20]

H3 states that the positive relation between the probability of CEO turnover and the absolute management forecast error holds when the CEO is less entrenched. Since there is no consensus measure for CEO entrenchment, we use three separate measures as proxies for CEO entrenchment. The first measure is the percentage of outstanding shares owned by the CEO. As CEO ownership decreases, the CEO exercises less power over board members and it becomes easier for the board to replace the CEO. We define *CEO_Own_Low* as 1 if CEO ownership percentage falls within the sample bottom quartile, and 0 otherwise. The results, presented in Panel A of Table 5 show that, consistent with H3, both the coefficient for the interaction of *Abs*(*MFE*) $*$ *MF* with *CEO_Own_Low*, γ_2, which captures the incremental effect of less entrenchment, and the sum of the coefficient for *Abs*(*MFE*) $*$ *MF* and the coefficient for the interaction, $\gamma_1 + \gamma_2$, which captures the full effect, are significantly positive.

---

[19] As noted by Ai and Norton (2003), the interpretation of interaction effects in logit and probit models can be problematic. To address this issue, we employ the Stata procedure recommended by Norton et al. (2004). Our results are robust to the alternative procedure.

[20] Richardson et al. (2004) find that analysts tend to issue more optimistic earnings forecasts at the beginning of the forecasting period than later in the period. Thus, some firms may be misclassified as poorly performing because of the analysts' bias. Our evidence indicates that boards are not likely to dismiss CEOs who issue inaccurate forecasts if the firm performance is good. Thus, if good-performance firms are misclassified as poorly performing, then we are less likely to find the positive relation between CEO turnover and the absolute management forecast error in the poor-performance group. In addition, when we use alternative 12-month or 24-month performance measures, such as market returns and earnings changes to classify firms as poorly performing, our results remain robust.

*, **, *** $p < 0.10$, $p < 0.05$, and $p < 0.01$, respectively (based on one-tailed levels of significance).

This table presents the results of bivariate probit regressions estimated simultaneously. The dependent variable for the first-stage regression, *MF*, is included as an independent variable in the second-stage (CEO turnover) regression. For parsimony, the intercepts are not reported in the table. Variable definitions are in Table 2. We adjust Z-statistics and p-values for time-series correlation.

Our second measure of entrenchment is CEO duality, indicating that the CEO also serves as the chairman of the board. CEOs who do not hold the dual positions are likely to wield a weaker influence over the board's decision on CEO replacement. We therefore define *Chair_Non_Dual* as equal to 1 if the CEO does not serve as board chair. The results in Panel B of Table 5 show that the incremental effect captured by γ_2 is insignificant even though the full effect captured by $\gamma_1 + \gamma_2$ is significantly positive when the CEO does not serve as chairman.

(continued on next page)

Our third measure of CEO entrenchment is CEO tenure. CEOs with shorter tenure have had less time to influence the selection of board members and are therefore more vulnerable to being replaced based on signals of poor performance. We therefore define *Tenure_Low* as equal to 1 if the

CEO's tenure falls within the sample bottom quartile and predict that the interaction of *Tenure_Low* with *Abs(MFE)* is positive. Panel C of Table 5 presents the results. Consistent with H3, γ_2 and $\gamma_1 + \gamma_2$ are significantly positive when CEOs have shorter tenure.

Overall, the results in Table 5 generally support the prediction that the impact of management forecast accuracy on CEO turnover is stronger when CEO entrenchment is relatively low. In

For parsimony, the intercepts are not reported in the table. Definitions of other variables are in Table 2. We adjust Z-statistics and p-values for time-series correlation.

Variable Definitions:
CEO_Own_Low = 1 if CEO ownership percentage falls within the sample bottom quartile, and 0 otherwise;
Chair_Non_Dual = 1 if the CEO does not have the Chairman title, and 0 otherwise; and
Tenure_Low = 1 if CEO tenure falls within the sample bottom quartile, and 0 otherwise.

untabulated tests we conduct sensitivity tests using three alternative measures of CEO entrenchment that aggregate CEO ownership, CEO duality, and CEO tenure. Specifically, we (1) use the continuous values of CEO ownership and CEO tenure variables, and the CEO duality indicator variable to construct a common factor through principle components analysis; (2) construct a new variable by summing the three indicator variables, *CEO_Own_Low*, *Chair_Non_Dual*, and *Tenure_Low*; and (3) create a new indicator variable equal to 1 if any of the three individual indicator variables is equal to 1. We rerun our tests using these alternative measures and find the results remain robust. Our results are also robust to using industry-adjusted CEO ownership and tenure.

Additional Tests

This section investigates four additional issues related to the impact of management forecast accuracy on CEO turnover: (1) whether the impact depends on the sign of the management forecast error, (2) whether the impact is conditional on the underlying uncertainty about future earnings, (3) whether the impact reflects managers' ability to manage earnings rather than their ability to forecast earnings, and (4) whether management forecast accuracy as a measure of CEO ability predicts future CEO turnover.

First, we investigate whether the impact of management forecast accuracy on CEO turnover depends on the sign of management forecast error. Although we include a broad range of controls for overall performance, it is conceivable that a negative management forecast error (actual earnings below a management forecast) proxies for poor performance. According to this logic, the magnitude of positive management forecast error should not be positively associated with the probability of CEO turnover. To test the validity of this argument, we modify Equations (2) and (3) to capture the signs of management forecast errors. In Equation (2), we add the interaction of $Abs(MFE) * MF$ with a dummy variable that is 1 if the management forecast error is negative (*MFE_Negative*) and add the interaction of $Abs(MFE) * MF$ with a dummy variable that is 1 if the management forecast error is positive (*MFE_Positive*). Panel A of Table 6 shows that the magnitudes of both positive and negative forecast errors are significantly related to CEO turnover. In addition, the difference between the coefficients on the positive and negative forecast errors is not significant. These results indicate that the positive association between the absolute management forecast error and the probability of CEO turnover continues to hold when actual earnings exceed the management forecast; i.e., when the forecast error is positive.

To further examine whether our results are driven by negative management forecast errors, in Panel B of Table 6 we present results from the estimation of a regression that augments Equation (3) by interacting the positive and negative management forecast errors with the good and poor performance dummy variables. This allows us to assess whether our results hold for both positive and negative forecast errors in each of good- and poor-performance groups. We find that the coefficients for the positive and negative forecast error interacted with the good performance dummy variable (*Dummy_Good*) are not significant, and not significantly different from each other. This suggests that when performance is good, management forecast error, either positive or negative, does not have a significant impact on CEO turnover. On the other hand, the coefficients for positive and negative forecast errors are significant when interacted with the poor performance dummy variable (*Dummy_Poor*), and the difference between the coefficients for the positive and negative forecast errors is not significant. These results suggest that when performance is poor, the magnitude of forecast error is significantly associated with CEO turnover, and that this applies to both positive and negative forecast error.

Our findings in Table 6 have implications for management's use of earnings forecasts to lower the market's expectation of earnings. Prior literature documents that CEOs have an

incentive to opportunistically issue overly pessimistic earnings forecasts to dampen investor expectations and to increase the probability of positive earnings surprises (Matsumoto 2002; Cotter et al. 2006). Our study suggests a potential cost to this strategy. If the firm issues a forecast to guide down the analyst forecast, then investors might suspect that the CEO is attempting to

*, **, *** $p < 0.10$, $p < 0.05$, and $p < 0.01$, respectively (based on one-tailed levels of significance).
This table presents the results of bivariate probit regressions estimated simultaneously. The dependent variable for the first-stage regression, *MF*, is included as an independent variable in the second-stage (CEO turnover) regression. For parsimony, the intercepts are not reported in the table. Definitions of other variables are in Table 2. We adjust Z-statistics and p-values for time-series correlation.

Variable Definitions:
MFE_Positive = 1 if the management forecast error is positive, and 0 otherwise;
MFE_Negative = 1 if the management forecast error is negative, and 0 otherwise;
Dummy_Good = 1 if *AFE* is not negative (i.e., the firm reports earnings above the analyst forecast), and 0 otherwise; and
Dummy_Poor = 1 if *AFE* is negative (i.e., the firm reports earnings below the analyst forecast), and 0 otherwise.

mislead the market or lacks the ability to make accurate earnings forecasts. This suspicion is likely reinforced if firms report overall poor performance, and, as a result, the board is more likely to replace the CEO.

We also investigate the impact of earnings uncertainty on the relation between management forecast accuracy and CEO turnover. Earnings uncertainty could affect the relation between management forecast accuracy and CEO turnover if the board adjusts management forecast accuracy for the underlying difficulty in accurate forecasting. To investigate this issue, we expand Equation (2) by adding an interaction between $Abs(MFE) * MF$ and a high earnings volatility dummy that is 1 if earnings volatility (*Earn_Vol*) is above the sample median. In untabulated results, the coefficient for $Abs(MFE) * MF$ is 0.421 and significantly positive ($p < 0.05$), but the coefficient for the interaction variable is 0.075 and insignificant. These results suggest that the relation between CEO turnover and management forecast accuracy does not depend on earnings volatility.

Management forecast error could reflect the ability to manage earnings rather than management's ability to form an accurate forecast. To explore this alternative explanation for our results, we follow Barton and Simko (2002) and assume that firms with relatively low net operating assets have the greatest ability to manage earnings. We find that $Abs(MFE) * MF$ is not significant for firms with low net operating assets (high earnings management potential), but remains significantly positive when net operating assets are high (earnings management is constrained). Thus, we conclude that the observed relation between management forecast accuracy and CEO turnover is more likely to reflect management's ability to forecast earnings than management's ability to manage earnings toward the forecast.

Our primary results are based on CEO turnover from 1996 to 2006. To investigate whether the results also apply to a more recent time period, we follow Beneish (1999) and use the parameter estimates from Equation (3) to predict turnover during a holdout period (2007–2010).[21] We then compare the results to a naive model and to the prediction model without the management forecast error variables.[22] Because a prediction model generates Type 1 (classifying an observation as no

---

[21] We also estimate the model using an expanded sample period that covers 1996–2010. We find that the primary results reported in Table 4 continue to hold. However, we observe some changes for control variables in the turnover model. Specifically, *Earn_Vol* becomes significantly positive and *Ret_Vol* becomes weakly significant. In addition, *Inst_Own* and *Chair_Dual* become insignificant.

[22] A naive model classifies CEOs as turnover or as non-turnover depending on the relative costs of Type 1 and Type 2 errors. The best naïve strategy is to classify all CEOs as no turnover if the relative costs of Type 1 and Type 2 are less than 40:1. The naïve strategy switches to classify all CEOs as turnover at 40:1.

TABLE 7
Application of Turnover Prediction Model to Holdout Sample

Relative Costs of Type 1 and Type 2 Errors (1)	Cutoff Probability (2)	Expected Cost of Type 1 Error (3)	Expected Cost of Type 2 Error (4)	Cost of Model Errors Relative to Naive Model (5)	Cost of Model Errors Relative to Model without Management Forecast Error (6)

10:1	0.9753	0.8482	0.0373	0.9974	1.0161
20:1	0.8347	0.5741	0.1502	0.9108	0.9653
30:1	0.7195	0.3796	0.2920	0.7645	0.9663
40:1	0.7276	0.3796	0.2920	0.7668	1.0189
60:1	0.8722	0.1969	0.5453	0.8756	0.9891
100:1	0.9720	0.0356	0.8654	0.9687	0.9882

We use the parameter estimates for the turnover prediction model in Table 4 based on the data for the period 1996–2006 to predict turnover during a holdout period 2007–2010. Column (1) presents the assumed relative cost of Type 1 (predicting no turnover when the CEO is replaced) and Type 2 errors (predicting turnover when the CEO is retained). Column (2) presents the cutoff probability of CEO turnover from the model that minimizes the cost of model errors. Columns (3) and (4) present the expected costs of Type 1 and Type 2 errors, respectively, for the model given the cut-off probabilities in Column (2) and the relative costs of errors in Column (1). Column (5) presents the cost of model errors relative to a naive model whereby the CEO is retained each quarter. Numbers less than 1 represent improvements over the naive model. Column (6) presents the cost of model errors relative to the model from Table 4 after removing the management forecast error terms. Numbers less than 1 indicate that including management forecast error improves the prediction model.

turnover when the CEO is dismissed) and Type 2 (classifying an observation as turnover when the CEO is retained) errors, it is necessary to specify the relative importance of each type of error in order to evaluate the overall performance of the prediction model. We follow Beneish (1999) and provide the results assuming different relative costs of Type 1 and Type 2 errors.[23]

We report the results in Table 7. Column (1) presents the relative costs of Type 1 and Type 2 errors used to evaluate the model. Column (2) provides the cut-off probability of turnover from the prediction model that minimizes the cost of the errors. Columns (3) and (4) provide the expected costs of Type 1 and Type 2 errors for each cut-off. The results in Column (5) show that the relative costs of errors using the prediction model relative to a naive model are consistently lower than 1. This provides evidence that the model, as a whole, reduces the cost of prediction error. The results in Column (6) show that the relative costs of errors are below 1 in four out of the six cases, where the cost of Type 1 error is greater than the cost of Type 2 error.[24] This is consistent with the prediction model with management forecast error tending to reduce the cost of prediction errors. It should be noted that the holdout sample period (2007–2010) corresponds to the economic downturn associated with the financial crisis, and the extent to which the crisis altered the underlying CEO replacement decision would add noise to the test.

---

[23] Since we do not know the true economic costs associated with a Type 1 or Type 2 error, we follow Beneish (1999) and allow for a wide range of relative costs for Type 1 and Type 2 errors. We note that our objective is to identify the economic factors that lead to CEO turnover, as opposed to developing a model that could be used to predict CEO turnover. Because it is difficult to assess a prediction model outside of a specific decision-making context, our results for the model prediction error should be interpreted with caution.

[24] Given that CEO turnover is an infrequent event (occurs in approximately 3 percent of our sample quarters), for all practical purposes a prediction model has value only if the cost of a Type 1 error is relatively high. Otherwise, it would be difficult to beat a naive model that predicts no turnover, which would be correct 97 percent of the time.

V. SUMMARY AND CONCLUSIONS

This paper investigates the empirical relation between management forecast accuracy and CEO turnover. We contend that the accuracy of the forecast issued by the firm reflects the managerial ability of the CEO. Accordingly, we predict that boards of directors use management forecast accuracy to update their beliefs regarding CEOs' managerial ability and incorporate the forecast accuracy into the decision to retain or replace the CEO. Further, we predict that this effect is more pronounced when the firm's financial performance is poor and when the CEO is relatively less entrenched. Our results generally support our predictions. We find a significantly positive relation between the probability of CEO turnover and the absolute value of management forecast error and that the relation is stronger when overall firm performance is poor, i.e., the firm misses the analyst forecast. We also find that the positive relation between CEO turnover and the absolute management forecast error is stronger when the CEO is less entrenched. The positive relation between CEO turnover and the absolute management forecast error for poorly performing firms also appears to hold when earnings exceed the management forecast and when earnings are below the forecast. Overall, our results suggest that the boards use management forecast accuracy as an indicator of the CEOs' managerial ability and incorporate the forecast accuracy in the decision to retain or replace the CEO when firm performance is poor.

Our study adds new insight into management's incentives to issue accurate forecasts by documenting a labor market consequence of inaccurate management forecasts. Our results suggest that the labor market penalizes managers for inaccurate forecasts and that managers with low ability bear a cost from issuing inaccurate forecasts. In addition, our study suggests that the board holds the CEO responsible for the accuracy of the firm's earnings forecasts.

The Effect of Financial Analysts' Strategic Behavior on Analysts' Forecast Dispersion

Xiaohui Gloria Liu
John Carroll University

Ramachandran Natarajan
The University of Texas at Dallas

ABSTRACT: Financial analysts' forecast dispersion has been used in a variety of contexts in accounting and finance studies. In this study, we provide large sample evidence on the cross-sectional determinants of forecast dispersion and examine to what extent analysts' strategic behavior biases the observed dispersion from the dispersion of unmanaged forecasts. We propose a method to estimate the dispersion bias for each sample observation. We find that observed dispersion, on average, understates dispersion of unmanaged forecasts by 53.4 percent and this downward bias varies considerably across firms. We further discuss the implications of the significant cross-sectional variation in the bias in observed dispersion for studies that rely on dispersion to estimate constructs such as consensus and information quality as well as those that use dispersion directly in research design.

I. INTRODUCTION

A variety of empirical applications in accounting and finance have used measures of the dispersion of financial analysts' earnings forecasts. Despite the widespread use of forecast dispersion in accounting and finance research, very little evidence exists on the cross-sectional determinants of this important empirical measure (an exception is Diether et al. [2002]). Observed forecasts data are not only influenced by characteristics such as public and private information precision, but also by analysts' strategic behavior. Prior research has mainly examined two different types of analysts' strategic actions, namely, herding and self-selection. Herding (Trueman 1994; Hong et al. 2000; Clement and Tse 2005) occurs when analysts

strategically process proprietary and public information to generate forecasts that are closer to recent forecasts of other analysts. Self-selection, on the other hand, arises when a subset of analysts whose information processing results in low forecasted earnings choose not to release their forecasts (McNichols and O'Brien 1997; Hayes 1998; Hayes and Levine 2000). In contrast to prior research that has investigated the effect of the above types of analysts' strategic behavior on forecast accuracy, we examine the impact of analysts' strategic behavior on forecast dispersion in the cross-section.

We first discuss the implications of different types of analysts' strategic actions for their effect on dispersion and show that the bias induced in observed dispersion may be positive or negative depending on the context. For example, if analysts strategically herd toward a consensus of unmanaged forecasts, then it may lead to an estimate of dispersion derived from observed forecasts data that is lower than the dispersion based on unmanaged forecasts.[1] On the other hand, if some of the analysts strategically follow a "leader" analyst who is making a bold forecast away from the consensus, then observed dispersion will be higher than the dispersion of unmanaged forecasts. Finally, if self-selection by analysts is the strategic behavior of choice, then it may lead to observed dispersion being lower than the dispersion of unmanaged forecasts.

We then estimate forecast dispersion for 89,473 observations (treating dispersion for the pre- and post-interim earnings announcement periods as two separate sample observations) by using a primary sample of analysts' annual earnings forecasts over the period 1985–2004. Our pooled cross-sectional analysis reveals that forecast dispersion is positively associated with book-to-market ratio, CAPM beta, earnings variation, reporting a loss, research and development expense, the standard deviation of residuals from the market model, number of analysts, the exchange-adjusted turnover in the firm's shares, and debt-to-equity ratio. We also find that forecast dispersion is negatively associated with market value of the firm, momentum, current period earnings change, and sales turnover ratio. These results are consistent with prior literature. We check for the existence of the bias in observed dispersion measures by modeling the unexplained portion of forecast dispersion as arising due to both a two-sided random noise component and a one-sided random component and find support for the argument that observed forecast dispersion suffers, on average, from a *downward* bias.

We also calculate this downward bias for each sample observation using the conditional mean estimator of the one-sided component of the error. By adjusting the observed dispersion for this downward bias, we derive a modified dispersion measure. On average, the bias understates the dispersion of unmanaged forecasts by 53.4 percent, indicating that the adjustment we propose is both economically and statistically significant. In addition, we also show that a set of firm and analyst characteristics that have been identified in prior research as being associated with analysts' herding and self-selection behavior can explain cross-sectional variation in this dispersion bias.

More importantly, we demonstrate that using our modified dispersion measure instead of the observed dispersion measure leads to significantly different inferences in a number of research settings. Specifically, we show that inferences about the relative magnitude of the change in public and private information quality around quarterly earnings announcements reverse by using our modified dispersion measure. We also document that the consensus or commonality measure derived from observed dispersion is significantly higher than the corresponding measure derived from our dispersion measure. We further predict and find support for the hypothesis that this upward bias in consensus is significantly larger for those firms that have higher herding tendency, higher variation in analyst capabilities, higher levels of financial distress, and higher levels of forecast optimism. We also show that use of our measure leads to significantly different conclusions about the association between cost of equity capital and public and private information quality compared to results based on observed dispersion. Finally, we also discuss why it is critical for studies that develop and test competing hypotheses about the predicted association between a specific variable of interest and dispersion to perform a robustness check of their results with our modified dispersion measure.

---

[1] For the rest of the paper, the term "unmanaged forecast" refers to a forecast made by a rational analyst who is an efficient information processor and does not indulge in strategic behavior.

We believe that our study makes the following contributions to the literature on analysts' forecast dispersion. First, it provides large-sample evidence on the determinants of forecast dispersion and confirms that analysts' strategic behavior induces, on average, a downward bias in the dispersion measure. Second, it develops an adjustment procedure that can help correct the bias in observed dispersion. Third, it illustrates the importance of our modified dispersion measure for a variety of studies that employ proxies of analysts' information environment derived from dispersion, as well as those that use dispersion directly in their research design.

Section II provides a review of the relevant literature on forecast dispersion and analysts' strategic behavior, and discusses the research questions. Section III discusses the research methodology used in the paper. We discuss sample selection and the empirical results in section IV. Section V provides empirical demonstrations of settings where our modified measure of dispersion yields different inferences and discusses the implications of these empirical findings for accounting and finance research. We provide a summary and conclude in section VI.

II. LITERATURE REVIEW AND RESEARCH QUESTION

This section first reviews and summarizes the relevant literature in accounting and finance that has used analysts' forecast dispersion as part of the research design. We then provide background information on analysts' strategic behavior and discuss its effect on dispersion in the cross-section.

Use of Dispersion in Accounting and Finance Research

The widespread use of analysts' forecast dispersion in accounting and finance empirical research is primarily due to the fact that dispersion, as a theoretical construct, can be expressed as a product of the overall level of uncertainty and divergence in analysts' beliefs or lack of consensus (Barry and Jennings 1992; Abarbanell et al. 1995; Barron et al. 1998). Therefore, various empirical studies have used observed forecast dispersion as a proxy for uncertainty as well as a proxy for the divergence in analysts' beliefs.

Earlier empirical studies that have used forecast dispersion include Daley et al. (1988), who examine the association between forecast dispersion and *ex post* magnitude of unexpected earnings, *ex post* returns variance around earnings announcement dates, and the average variance of return to maturity of options. Likewise, Stickel (1989) analyzes the association between pre-earnings announcement forecast dispersion and post-announcement analysts' revision activity, and Ajinkya et al. (1991) use forecast dispersion as a proxy for divergence in beliefs and conclude that a significant positive association exists between the dispersion of analysts' forecasts of annual EPS and trading volume.[2]

An influential study by Barron et al. (1998; hereafter, BKLS) has led to an increased research focus on the roles of dispersion and the squared error in mean forecast. Assuming that all analysts following a particular firm are endowed with private information of the same quality, the BKLS approach can be used to develop proxies for private and public information quality at various points in time. Recent studies that have used the BKLS approach include Barron et al. (2002), who find that the precision of public information contained in analysts' forecasts increases more than the precision of private information around earnings announcements, Bowen et al. (2002), who document that conference calls can improve analysts' private information precision, Liang (2003) who concludes that post-earnings announcement drift is mainly driven by investors' irrationally assigning too much weight to their private information, and Botosan et al. (2004), who investigate the association between implied cost of capital and the quality of public and private information.

---

[2] Other accounting studies such as Swaminathan (1991), Imhoff and Lobo (1992), Lustgarten and Mande (1998) and Barron and Stuerke (1998) also use dispersion prominently in their research design.

Studies in finance that rely on the dispersion measure include Diether et al. (2002), who find that stocks with higher dispersion in analysts' earnings forecasts earn lower future returns and interpret their evidence as suggesting that a high level of disagreement can result in overvaluation. However, Johnson (2004) argues that Diether et al.'s (2002) evidence may be due to dispersion proxying for idiosyncratic rather than systematic risk. Thomas (2002) investigates the relation between an asset-based Herfindahl Index and forecast dispersion and concludes that greater business diversification is not associated with increased asymmetric information. Zhang (2006) includes forecast dispersion in his research design to quantify information uncertainty while examining the role of information uncertainty in price continuation anomalies and cross-sectional variations in stock returns.

Despite the popularity and widespread use of analysts' forecast dispersion in accounting and finance research, few studies, except for Diether et al. (2002), have examined the cross-sectional determinants of dispersion. Diether et al. (2002) attempt to disentangle the effect of dispersion in analysts' forecasts from stock fundamentals and additional measures of risk by performing a series of cross-sectional regressions of dispersion on various lagged firm characteristics. They conduct their analysis at the annual level and use only a small fraction of all available analyst forecasts for a particular firm. Their study also does not consider the effect of factors other than overall level of uncertainty and divergence of opinion on dispersion.

Impact of Analysts' Strategic Behavior on Observed Dispersion

An important factor that may affect the use of dispersion based on observed analysts' forecasts is possible strategic behavior by some of the analysts issuing the earnings forecasts. Strategic behavior from individual analysts may manifest itself in a number of ways, with different implications for the dispersion among observed forecasts. For example, consider a single analyst who completely ignores her private information when issuing a revised forecast and simply issues a revised forecast equal to the consensus based on unmanaged forecasts of other analysts. It is intuitive that this type of strategic behavior, i.e., reporting the unbiased consensus forecast, will always lead to observed dispersion being strictly lower than the dispersion of unmanaged forecasts.

On the other hand, if the marginal analyst decides to follow a leader by copying the leader's forecast, then the observed dispersion may be lower or higher than the dispersion based on unmanaged forecasts. Given that very little guidance exists in prior literature on how strategic behavior of "follower" analysts affects observed dispersion, we examine stylized situations characterized by the presence of two or three analysts to provide further insight into this issue. The intuitive case of two analysts, where one analyst simply adjusts her forecast to be closer to the leader's forecast, leads to a strict reduction in dispersion. However, with three analysts, the situation becomes more complex; Appendix A presents nine different three-analyst scenarios in which one or more analysts follow a leader analyst. In seven out of these nine scenarios, observed dispersion is smaller than the dispersion of unmanaged forecasts. These scenarios include situations where the follower analysts have initial extreme forecasts as well as when two of three analysts follow the third who is the leader. The only situations where observed dispersion exceeds dispersion of unmanaged forecasts occur when a strategic analyst in the middle of the pack follows one of the extreme analysts.

It is also possible that a downward bias is induced in observed dispersion if a subset of analysts choose not to revise their forecasts when endowed with bad news. This self-selection behavior (McNichols and O'Brien 1997; Hayes 1998; Hayes and Levine 2000) will not only produce a mean forecast that is higher than the mean of the unmanaged forecasts, but also result in a lower level of observed dispersion relative to the dispersion of unmanaged forecasts.

The discussion in this section suggests that analysts' strategic behavior generally leads to convergence of their forecasts and, on average, *downward* bias in the dispersion of analysts' forecasts. The next section proposes a method for evaluating whether observed dispersion exhibits a downward bias and develops a modified measure of forecast dispersion that captures only the overall level of uncertainty and divergence of opinion.

III. METHODOLOGY

Consider at time t, observations on $i = 1,\ldots,I$ firms, each observation comprising a vector of observed individual analysts' forecasts $Y_{it} \equiv (y_{1it},\ldots,y_{Nit})$ and a vector of firm-characteristics $X_{it} \equiv (x_{1it},\ldots,x_{Kit})$. We denote the dispersion in observed forecasts as $\tilde{D}_{it}$, and the dispersion of the unobserved analysts' forecasts in the absence of any strategic action as D_{it}, which is made up of a random zero mean noise term v_{it} and a systematic component that can be explained by the firm characteristics. Specifically:

$$D_{it} = \beta_0 + \sum_{k=1}^{K} \beta_k x_{kit} + v_{it}. \tag{1}$$

Assuming that the observed dispersion $\tilde{D}_{it}$will be less than D_{it}, the dispersion based on unmanaged forecasts, we represent the positive difference between the dispersion of unmanaged forecasts and the observed dispersion as the one-sided random error term $u_{it} \geq 0$, i.e.:

$$\tilde{D}_{it} = D_{it} - u_{it} = \beta_0 + \sum_{k=1}^{K} \beta_k x_{kit} + v_{it} - u_{it}. \tag{2}$$

We assume that the error terms v_{it} and u_{it} are independent and identically distributed (i.i.d.) random variables across t and i, independent of each other and the various firm characteristics. For a major part of the rest of the discussion, we suppress the firm and time subscripts on the random error terms v_{it} and u_{it} and denote the total error $v - u$ as ε.[3]

It is straightforward to verify that the probability density function (pdf) of the total error, ε, is given by:

$$f_\varepsilon(\varepsilon) = \int_{\varepsilon}^{\infty} f_v(v) f_u(v - \varepsilon)\, dv, \tag{3}$$

where $f_v(v)$ and $f_u(u)$ are the pdf's of v and u, respectively. The unknown parameters in Equation (2) can be estimated through Maximum Likelihood (ML) estimation if a specific parametric form is assumed for the pdf of ε.[4] Assume that v is distributed as $N(0, \sigma_v^2)$and u as half-Normal i.e., as

---

[3] If prior beliefs dictate that observed dispersion is greater than the dispersion of unmanaged forecasts, i.e., analysts' strategic behavior creates additional divergence, then the specification in Equation (2) can be modified by adding rather than subtracting the one-sided error term u_{it}. The total error ε, in this case, will be $v + u$.

[4] Ordinary Least Square (OLS) method can be used to estimate β_k ($k = 1$ to K) since ε has a finite variance, although it may not have a zero mean (Schmidt 1976). The OLS estimators of β_k ($k = 1$ to K) are consistent. However, the OLS intercept is an inconsistent estimator of β_0. The OLS intercept has a negative bias because it forces the error term to have a mean of zero despite the fact that the error term has a non-zero negative mean. If we denote the OLS intercept as δ_0, then plim $\hat{\delta}_0 = \beta_0 - E(u)$ where $E(u)$ is the expected value of u.

$N^{+}(0, \sigma_u^2)$ as in Aigner et al. (1977) or Meeusen and van den Broeck (1977).[5] Then the domain of the total error ε is (–∞, ∞), and the pdf of ε is:

$$f(\varepsilon) = \frac{2}{\sigma}\phi\left(\frac{\varepsilon}{\sigma}\right)\Phi\left(-\frac{\varepsilon\lambda}{\sigma}\right), \tag{4}$$

where $\sigma = (\sigma_u^2 + \sigma_v^2)^{1/2}$, $\lambda = \frac{\sigma_u}{\sigma_v}$, and $\Phi(.)$ and $\varphi(.)$ are the standard normal cumulative distribution and density functions.[6]

Maximum Likelihood (ML) estimation of Equation (2) using the pdf of ε in Equation (4) provides estimators of β_0, β_k ($k = 1$ to K), σ_u and σ_v that are consistent, asymptotically normally distributed and efficient.[7] The maintained assumption of reduction in dispersion due to analysts' strategic behavior can be evaluated by (a) examining the t-statistic associated with σ_u, and (b) comparing whether ML estimation of Equation (2) generates a significantly higher likelihood than an Ordinary Least Squares (OLS) estimation of Equation (2).

The estimated value of the observation-specific total error term ε_{it} and the estimated values of the parameters σ_u and σ_v can be combined to generate a point estimator of u_{it}. Specifically, the conditional density of u given ε i.e.: $f(u|\varepsilon)$ can be derived as:

$$f(u|\varepsilon) = \exp\left(-\frac{(u-\tilde{\mu})^2}{2s^2}\right) \Big/ \sqrt{2\pi}s\left[1 - \Phi\left(-\frac{\tilde{\mu}}{s}\right)\right], \tag{5}$$

where $\tilde{\mu} = -\frac{\varepsilon\sigma_u^2}{\sigma^2}$, $s^2 = \frac{\sigma_u^2\sigma_v^2}{\sigma^2}$, and $\sigma^2 = (\sigma_u^2 + \sigma_v^2)$. Since $f(u|\varepsilon)$ is distributed as $N^{+}(\tilde{\mu}, s^2)$, one can use the mean of the distribution in Equation (5) as a point estimator for u (Jondrow et al. 1982). Specifically, the conditional mean can be evaluated as:

$$E(u_{it}|\varepsilon_{it}) = s\left[\frac{\phi\left(\frac{\varepsilon_{it}\lambda}{\sigma}\right)}{1 - \Phi\left(\frac{\varepsilon_{it}\lambda}{\sigma}\right)} - \frac{\varepsilon_{it}\lambda}{\sigma}\right]. \tag{6}$$

We add $E(u_{it}|\varepsilon_{it})$, the conditional mean of u (which is strictly positive), to the observed dispersion to generate the observation-specific "corrected" dispersion measure.

We next discuss the sample selection, ML estimation of the cross-sectional determinants of observed dispersion, the empirical distribution of the dispersion bias, and an exploratory analysis of the cross-sectional determinants of the dispersion bias.

---

[5] The original Aigner et al. (1977) study suggests normal distribution for v and either the half-normal distribution or the exponential distribution for u. Besides yielding simple closed-form pdf for the total error ε (see Equation (4)) these basic pdf's also provide closed-form pdf for the conditional density of u given ε. The advantage of using half-normal or exponential pdf's for u is that they are both one-parameter distributions. As a result, the pdf for the total error ε (which is also commonly referred to as composed error in the empirical production economics literature) is characterized by just two parameters i.e., σ_u and σ_v. Interestingly, the Aigner et al. (1978) study, while more than 30 years old, continues to provide a robust platform and influence empirical production economics research. A recent Google Scholar search for this study revealed that it has been cited more than 3,200 times.

[6] For the case of observed dispersion being greater than the dispersion of unmanaged forecasts, $\varepsilon = v + u$ and the pdf of the composed error term is $f(\varepsilon) = \frac{2}{\sigma}\phi(\frac{\varepsilon}{\sigma})\Phi(\frac{\varepsilon\lambda}{\sigma})$.

[7] The error, ε, can be expressed as $\tilde{D}_{it} - \beta_0 - \sum_{k=1}^{K}\beta_k x_{kit}$ from Equation (2) and substituted in the pdf in Equation (4) to evaluate the likelihood for every observation. ML estimation involves maximizing the joint likelihood, which is the product of the individual likelihood values by choosing appropriate values for β_0, β_k ($k=1$ to K), σ_u and σ_v. ML estimation routines are available in statistical packages such as STATA, Gauss, R, and SAS. We used Proc NLP in SAS to carry out our maximum likelihood estimation.

IV. EMPIRICAL ANALYSIS

We first describe the criteria we used to select our sample. We start with the full Institutional Broker Estimate System (I/B/E/S) database and use the I/B/E/S Unadjusted Detail Earnings Estimate History File to obtain analysts' annual earnings forecasts, actual earnings, and actual stock price before any stock-split for the period from 1985 to 2004.[8] We focus on only those annual earnings forecasts issued within a 45-day window prior to quarterly earnings announcement or within a 30-day post-announcement window in the analysis. We therefore retain only those forecasts for which the interim quarterly earnings announcement date information is available in quarterly Compustat primary, supplementary, or tertiary files. If a particular analyst made multiple forecasts within a window, then we retain only the one closest to the announcement. If an analyst does not revise her forecast after the quarterly earnings announcement, then we assume she does not change her forecast. We also keep only those windows that had at least two analysts' forecasts for the firm. Using the forecasts within a particular pre- or post-announcement window, we calculate the mean forecast (*MEAN*) and the sample standard deviation (*STD*) of the forecasts.

The above procedure leads to a maximum of six observations (pre or post windows corresponding to each of the three quarterly announcement dates) per firm per year and 116,354 observations in the whole sample. Of these, we lose 26,097 observations due to non-availability of data for one or more of the various explanatory or control variables, leaving 90,257 observations with complete data. We further trim the data set by deleting observations that had extreme analysts' forecasts, which we define as those with forecast error scaled by price in the top or bottom half percentile in each fiscal year, leaving a final sample of 89,473 observations, ranging from 2,167 observations in 1985 to 7,375 observations in 2004.

Table 1 provides the descriptive statistics for some of the primary variables used in subsequent analysis. The average mean forecast is \$1.21 per share and the standard deviation is \$0.08 per share. The empirical distribution of standard deviation is left-skewed and 3,390 of the 89,473 observations (4 percent) have a sample standard deviation of zero. The median market value of equity is approximately \$935 million and median book-to-market ratio is 0.47. The median firm had a following of four analysts and 27 percent of the firms had non-zero R&D expenditure. Overall, the sample firms appear similar to those in prior large-sample studies based on I/B/E/S analysts forecast data.

Cross-Sectional Determinants of Dispersion

To examine whether observed dispersion is downward biased, we employ the following specification:[9]

$$\begin{aligned} Log(STD_{it}) = {} & \beta_0 + \beta_1 SIZE_{it} + \beta_2 BM_{it} + \beta_3 BETA_{it} + \beta_4 MOMENT_{it} + \beta_5 VAREPS_{it} \\ & + \beta_6 \Delta EPS_{it} + \beta_7 LOSS_{it} + \beta_8 RD_{it} + \beta_9 SDRES_{it} + \beta_{10} LOGNANALYST_{it} \\ & + \beta_{11} TURN_{it} + \beta_{12} DE_{it} + \beta_{13} SA_{it} + \beta_{14} LOG(ABSM)_{it} + \beta_{15} LOGP_{it} + v_{it} \\ & - u_{it}. \end{aligned} \tag{7}$$

---

[8] Using I/B/E/S detail file with already split-adjusted data does not change our results.

[9] The idea behind the log transformation is to make the data approximately normal. Since some of our observations have a standard deviation equal to zero, we add a small constant to all the standard deviation values before taking the logarithm. Berry (1987) suggests the choice of a constant that minimizes the sum of the absolute values of skewness and excess kurtosis. We fitted a 3-parameter log-normal distribution to the full dispersion data (including the zero dispersion observations) and chose the negative of the threshold value as the constant such that the resulting distribution of *log*(*STD* + *constant*) is approximately normal. The sum of the absolute values of skewness and excess kurtosis is very small at 0.09.

SA	0.241	0.190	0.098	0.216	0.328

The sample consists of 89,473 observations for the period 1985–2004. For each firm-quarter, there has to be at least two analysts' forecasts of annual earnings within 45 days before the quarterly earnings announcement, and within 30 days after the announcement. Pre- and post-announcement are considered two different observations. If an analyst does not revise her forecast after the quarterly earnings announcement, then we assume she does not change her forecast. If an analyst makes multiple forecasts within a measurement window, then the one closest to the announcement date is used.

Variable Definitions:
MEAN = mean of individual analysts' earnings forecasts;
STD = standard deviation of individual analysts' earnings forecasts;
SIZE = natural log of market value;
BM = book-to-market ratio;
BETA = beta calculated using a market model, based on monthly returns over the past 36 to 60 months before the quarterly earnings announcement;
MOMENT = cumulative monthly return calculated over the (−12,−2) window before the quarterly earnings announcement;
VAREPS = variance of the past eight quarters' earnings per share calculated in a rolling window;
ΔEPS = change in annual earnings per share, scaled by last fiscal year's closing price;
LOSS = 0 if quarterly earnings per share are positive or 0, 1 otherwise;
RD = 1 if the company reports research and development expense, 0 otherwise;
SDRES = standard deviation of the residual from the market model that estimated *BETA*;
LOGNANALYST = natural log of number of analysts who release forecasts in the measurement window;
TURN = mean daily turnover measured over the past 250 days, lagged one month, before the quarterly earnings announcement, adjusted for the average exchange daily turnover. Turnover is calculated as volume divided by shares outstanding;
DE = debt to equity; and
SA = sales to total assets.

We use explanatory variables from prior studies to capture cross-sectional variation in dispersion induced by firm-level variables proxying for characteristics such as fundamental risk, uncertainty, and difference in opinion. The fundamental risk variables we include are *SIZE* (measured as the natural log of market value of equity), CAPM *BETA*, book-to-market ratio (*BM*), and the cumulative return over an 11-month period ending two months before the earnings announcement (*MOMENT*). Based on the empirical evidence in Diether et al. (2002), we expect dispersion to be positively associated with *BETA* and *BM* but negatively associated with *SIZE* and *MOMENT*. Similar to Diether et al. (2002), we use turnover in the firm's shares (*TURN*) and the natural logarithm of the number of analysts (*LOGNANALYSTS*) as proxies for differences in opinion and expect them to be positively associated with dispersion.

We include past earnings variability (*VAREPS*), change in annual EPS from prior year (ΔEPS), an indicator variable for firms reporting a loss (*LOSS*), an indicator variable for firms that invest in R&D (*RD*), and standard deviation of market model residuals (*SDRES*) to capture the uncertainty in the analysts' information environment. We also include debt-to-equity ratio (*DE*) and sales turnover ratio (*SA*) as additional control variables. To control for the fact that firms with a high level of earnings may mechanically have a high level of dispersion, we also include the log of the absolute mean forecast, *LOG*(*ABSM*). In addition, we include the log of stock price (*LOGP*) as an additional control variable to account for any other correlated, omitted determinants of dispersion.[10] Brown and Han (1992) show that forecast dispersion decreases after earnings announcements and Barron et al. (2002) document that forecast dispersion decreases over time when one goes from the first quarter to the third quarter as analysts obtain more information. We include indicator variables that specify whether the observation belongs to Q1pre-announcement, Q1post-announcement, Q2pre-announcement, Q2post-announcement, or Q3pre-announcement windows to capture these effects. Finally, we also incorporate industry and year fixed-effects in the estimation.

The results in the first two columns of Table 2 of estimating Equation (7) using OLS are consistent with the evidence shown in prior studies on the determinants of forecast dispersion. All the explanatory variables have the predicted signs with the absolute values of many of the associated t-statistics being greater than 20. The model has good explanatory power with an adjusted R^2 of 0.392.

Next, using ML estimation based on the error term in Equation (5) yields estimated coefficients on the explanatory variables in the last two columns of Table 2 that are similar to those under OLS. The intercept term, however, shows a significant increase, consistent with the idea that the one-sided error term makes a significant contribution to the composed error structure. More specifically, the estimated value of σ_u, the parameter associated with the one-sided error term, is 0.962 with an associated t-statistic of 81.69. This provides support for the argument that the observed dispersion of analysts' forecasts is, on average, *less* than the dispersion based on the unmanaged forecasts. Additional evidence on the superiority of the composed error specification is provided by the likelihood ratio test. The Chi-square statistic with one degree of freedom for the likelihood ratio test has a value of 947, which is well above the 99 percent critical value of 6.63. Finally, the Schwartz index associated with the comparison of the ML specification with that of a benchmark OLS specification has a value of 468, which is significantly greater than the critical value of 10, once again providing evidence on the superiority of the composed error-model.[11]

Dispersion Bias Factor (DBF) and its Empirical Characteristics

Using the ML parameter estimates of the coefficients on the explanatory variables, we next calculate the residual error for every observation in the sample. We then use the residual error with the estimates of σ_u and σ_v to generate observation-specific, strictly positive, correction using the

---

[10] Prior studies have typically used a scaled measure of dispersion with absolute mean forecast or price as the deflator. Our primary interest in this paper is to develop a method to provide a correction to the observed dispersion measure. Therefore, instead of scaling dispersion by absolute mean forecast or price, we include both as control variables.

[11] The Schwartz index is calculated as $\{ML\ loglikelihood - OLS\ loglikelihood - 0.5log\ (n)\}$ where n is the total number of observations. For large samples, values of this index exceeding 10 indicate that the composed error model is favored over the OLS model.

Tests Comparing ML estimators with OLS estimators:

Likelihood Ratio Test: Chi-square = 947 (p-value < 0.01).

Schwartz index: 468 (Greater than critical value 10).

This table presents the pooled-regression results for OLS and ML estimation procedures respectively for the specification including year and industry fixed effects:

$$\begin{aligned} Log(STD_{it}) = {} & \beta_0 + \beta_1 SIZE_{it} + \beta_2 BM_{it} + \beta_3 BETA_{it} + \beta_4 MOMENT_{it} + \beta_5 VAREPS_{it} + \beta_6 \Delta EPS_{it} + \beta_7 LOSS_{it} \\ & + \beta_8 RD_{it} + \beta_9 SDRES_{it} + \beta_{10} LOGNANALYST_{it} + \beta_{11} TURN_{it} + \beta_{12} DE_{it} + \beta_{13} SA_{it} \\ & + \beta_{14} LOG(ABSM)_{it} + \beta_{15} LOGP_{it} + v_{it} - u_{it}. \end{aligned}$$

The sample consists of 89,473 observations for the period 1985–2004. For each firm-quarter, there has to be at least two analysts' forecasts of annual earnings within 45 days before the quarterly earnings announcement, and within 30 days after the announcement. Pre- and post-announcement are considered two different observations. If an analyst does not revise her forecast after the quarterly earnings announcement, then we assume she does not change her forecast. If an analyst makes multiple forecasts within a measurement window, then the one closest to the announcement date is used.

Variable Definitions:

STD = standard deviation of individual analysts' earnings forecasts;

(continued on next page)

TABLE 2 (continued)

SIZE = natural log of market value;
BM = book-to-market ratio;
BETA = beta calculated using a market model, based on monthly returns over the past 36 to 60 months before the quarterly earnings announcement;
MOMENT = cumulative monthly return calculated over the (−12,−2) window before the quarterly earnings announcement;
VAREPS = variance of the past eight quarters' earnings per share calculated in a rolling window;
ΔEPS = change in annual earnings per share, scaled by last fiscal year's closing price;
LOSS = 0 if quarterly earnings per share are positive or 0, 1 otherwise;
RD = 1 if the company reports research and development expense, 0 otherwise;
SDRES = standard deviation of the residual from the market model that estimated *BETA*;
LOGNANALYST = natural log of number of analysts who release forecasts in the measurement window;
TURN = mean daily turnover measured over the past 250 days, lagged one month, before the quarterly earnings announcement, adjusted for the average exchange daily turnover. Turnover is calculated as volume divided by shares outstanding;
DE = debt to equity;
SA = sales to total assets;
LOG(*ABSM*) = natural log of the absolute value of the mean forecasts;
LOGP = natural log of stock price;
Q1-PRE = 1 if the observation belongs to the (−45,−1) day window around earnings announcement of quarter 1, 0 otherwise;
Q1-POST = 1 if the observation belongs to the (0,29) day window around earnings announcement of quarter 1, 0 otherwise;
Q2-PRE = 1 if the observation belongs to the (−45,−1) day window around earnings announcement of quarter 2, 0 otherwise;
Q2-POST = 1 if the observation belongs to the (0,29) day window around earnings announcement of quarter 2, 0 otherwise; and
Q3-PRE = 1 if the observation belongs to the (−45,−1) day window around earnings announcement of quarter 3, 0 otherwise.

expression for the conditional mean in Equation (6).[12] Combining this correction with our dependent variable yields the corrected standard deviation (*STDMOD*).[13] For the rest of the paper, we define the fractional reduction in dispersion induced by analysts' strategic behavior as the dispersion bias factor, i.e., $DBF \equiv (STDMOD - STD)/STDMOD$[14] By construction, this factor takes values from 0 to 1 with large values denoting a greater level of downward bias in observed dispersion.

Panel A of Table 3 provides details on the empirical distribution of the observed dispersion (*STD*), the modified dispersion (*STDMOD*), and the dispersion bias factor (*DBF*). While the average observed dispersion is 0.076, the average modified dispersion is 0.133. Likewise, observed dispersion has a smaller standard deviation of 0.147 versus 0.220 for modified dispersion. On

---

[12] We examined the pair-wise correlations between the estimated conditional mean of u and each of the 15 independent variables. The average of these 15 correlations is −0.004, with ten of them being less than 0.01. This provides some support for the assumption that the one-sided error term u is independent of the firm characteristics.

[13] Given that the dependent variable is expressed in logarithmic form with a constant added to it (see footnote 9), we add the correction to the dependent variable, exponentiate it, and then subtract the constant to arrive at the corrected standard deviation. Since the correction is strictly positive, by construction, this procedure always generates a modified dispersion measure that is strictly greater than the observed dispersion measure.

[14] Instead of conditional mean $E(u_{it}|\varepsilon_{it})$, we also estimate conditional *mode* $M(u_{it}|\varepsilon_{it})$ to correct the dispersion bias, where the conditional mode is set equal to $-(\varepsilon_{it}\sigma_u^2)/\sigma^2$if $\varepsilon_{it} \leq 0$, and 0 otherwise (Jondrow et al. 1982). The resulting *DBF* values are highly correlated (Pearson and Spearman correlations exceeding 0.95) with the *DBF* values derived using the conditional mean estimator. We also use the alternative point estimator discussed in Battese and Coelli (1988) to estimate *DBF*. The resulting *DBF* measure is again found to be highly correlated with *DBF* calculated using the conditional mean estimator.

TABLE 3

Descriptive Statistics for Standard Deviation of Analysts' Earnings Forecasts, Modified Standard Deviation, and Dispersion Bias Factor (*DBF*)

Panel A: Overall Sample (n = 89,473)

	Mean	Standard Deviation	Lower Quartile	Median	Upper Quartile

The sample consists of 89,473 observations for the period 1985–2004. For each firm-quarter, there has to be at least two analysts' forecasts of annual earnings within 45 days before the quarterly earnings announcement, and within 30 days after the announcement. Pre- and post-announcement are considered two different observations. If an analyst does not revise her forecast after the quarterly earnings announcement, then we assume she does not change her forecast. If an analyst makes multiple forecasts within a measurement window, then the one closest to the announcement date is used.

Variable Definitions:
STD = standard deviation of individual analysts' earnings forecasts;
STDMOD = standard deviation adjusted for the downward bias in *STD*, where the bias is calculated for every sample observation based on the ML estimation of the following model:

$$\begin{aligned} Log(STD_{it}) = {} & \beta_0 + \beta_1 SIZE_{it} + \beta_2 BM_{it} + \beta_3 BETA_{it} + \beta_4 MOMENT_{it} + \beta_5 VAREPS_{it} + \beta_6 \Delta EPS_{it} + \beta_7 LOSS_{it} \\ & + \beta_8 RD_{it} + \beta_9 SDRES_{it} + \beta_{10} LOGNANALYST_{i,t} + \beta_{11} TURN_{it} + \beta_{12} DE_{it} + \beta_{13} SA_{it} \\ & + \beta_{14} LOG(ABSM)_{it} + \beta_{15} LOGP_{it} + v_{it} - u_{it};\ \text{and} \end{aligned}$$

DBF = Dispersion Bias Factor: $\frac{STDMOD-STD}{STDMOD}$.

average, the observed dispersion understates the dispersion based on unmanaged forecasts by 53.4 percent.[15] For a median representative firm, this understatement is 51.8 percent. Thus, our measure of dispersion bias appears to be both statistically and economically significant.

Panel B of Table 3 provides details on the year-wise distribution of average *DBF*. Interestingly, while the mean observed dispersion has steadily declined over time, the average *DBF* displays a more stable pattern. The trend over time in *DBF* seems to be slightly positive, providing some preliminary evidence that the downward bias may have increased a little bit over time.

Next, we analyze the factors that influence the variation in *DBF* in the cross-section. We focus on a set of eight firm and analyst characteristics that have been identified as being associated with analysts' herding and self-selection behavior. First, following Clement and Tse (2005), we identify forecasts as herding forecasts whenever a revised forecast falls between that analyst's prior forecast and the existing consensus forecast. We calculate *HERDING INTENSITY* on a firm-year basis as the number of herding forecasts divided by the total number of forecasts revisions. We predict a positive association between dispersion bias and *HERDING INTENSITY*.

We next introduce five firm-level measures of normalized variation in analysts' experience (*CV*(*EXPERIENCE*)), prior accuracy (*CV*(*ACCURACY*)), brokerage firm size (*CV*(*B_SIZE*)), forecasts' timeliness (*CV*(*TIMELINESS*)), and forecast frequency (*CV*(*FREQUENCY*)).[16] Hong et al. (2000) find that inexperienced analysts deviate less from consensus forecasts. Therefore, we predict that dispersion bias will be higher in firms with a high level of variation in the experience level of the analysts following the firm i.e., in firms with high *CV*(*EXPERIENCE*). It is also more likely that less capable analysts copy the star analysts' forecasts in those firms where there is wide variation in the capability of analysts. Therefore, we predict that dispersion bias will be increasing in *CV*(*ACCURACY*). High variability in the size of brokerage firms may lead to a greater level of dispersion bias, if one assumes that smaller brokerage firms employ lower-ability analysts who herd with the more capable analysts employed by bigger brokerage firms. We, therefore, predict a positive association between *CV*(*B_SIZE*) and dispersion bias. The possibility that the forecasts are clustered in time is positively related to a low level of variability in forecasts' timelines and frequency and since clustering is likely to be positively related to analysts' strategic behavior, we predict a negative association between dispersion bias and both *CV*(*TIMELINESS*) and *CV*(*FREQUENCY*).

---

[15] Using I/B/E/S Detail file with split-adjusted data yields an average *DBF* of 53.1 percent.

To account for the possibility that some of the dispersion bias may be due to self-selection behavior by analysts who abstain from releasing a forecast when they have bad news, we include two additional variables in the cross-sectional analysis. The results in McNichols and O'Brien (1997) and Hayes and Levine (2000) suggest a positive association between forecast optimism and self-selection. Our measure of analysts' optimism, denoted as *OPTIMISM*, is calculated as the difference between analysts' mean forecast and actual earnings, scaled by stock price. Suppression of bad news and the incidence of self-selection are likely to be relatively high in firms with a high level of financial distress, so we also include the Zmijewski (1984) distress score as an additional explanatory variable and predict a positive association between dispersion bias and *DISTRESS*.

The comparisons in Panel A of Table 4 reveal significant differences in the *DBF* between high and low groups of firms across the eight firm characteristics noted earlier. The average *DBF* is significantly smaller for the low group when compared to the high group in the case of *HERDING INTENSITY*, *CV*(*EXPERIENCE*), *CV*(*ACCURACY*), *DISTRESS*, and *OPTIMISM*. In contrast, the average *DBF* for the high group is significantly lower for *CV*(*B_SIZE*), *CV*(*TIMELINESS*), and *CV*(*FREQUENCY*).

Panel B of Table 4 provides results for a pooled cross-sectional regression of the *DBF* on the fractional rank of *HERDING INTENSITY*, the five firm-level analysts' heterogeneity measures (*CV*(*EXPERIENCE*), *CV*(*ACCURACY*), *CV*(*B_SIZE*), *CV*(*TIMELINESS*), and *CV*(*FREQUENCY*)), *DISTRESS*, and *OPTIMISM*. The regression is estimated at the firm-quarter level using all observations for which data on all eight explanatory variables are available. Year dummies as well as indicator variables for the points in time during the year when dispersion bias factor is estimated are included in the regression specification. All eight variables are found to be significantly associated with the dispersion bias. As predicted, we observe a positive association of dispersion bias with herding intensity, variation in analyst experience, variation in prior accuracy, financial distress, and analyst optimism. We also find that dispersion bias is negatively associated with variation in forecast timeliness and frequency. Contrary to our prediction, we observe a negative association between dispersion bias and variation in broker size. Analysts from smaller brokerage firms may try to differentiate themselves from their counterparts in bigger firms by communicating their true beliefs. This could be a possible explanation for this unexpected result.

---

[16] *CV*(.) denotes the coefficient of variation of a particular attribute and is measured as the standard deviation of that attribute divided by its mean.

TABLE 4

Empirical Characteristics of Dispersion Bias Factor (*DBF*)

---

*, ** The results indicate that $\mu_1 < \mu_2$ and $\mu_1 > \mu_2$, respectively.

Panel A presents the results of comparing *DBF* in different subsamples.

Panel B shows the results of pooled-regression for the following model:

$$DBF_{i,t} = \gamma_0 + \gamma_1 HERDING\ INTENSITY_{i,t} + \gamma_2 CV(EXPERIENCE)_{i,t} + \gamma_3 CV(ACCURACY)_{i,t} + \gamma_4 CV(TIMELINESS)_{i,t} + \gamma_5 CV(B\_SIZE)_{i,t} + \gamma_6 CV(FREQUENCY)_{i,t} + \gamma_7 DISTRESS_{i,t} + \gamma_8 OPTIMISM_{i,t} + error_{i,t}.$$

We use the fractional rank for all the independent variables. We also include year dummy and year-time dummy (*Q1-PRE, Q1-POST, Q2-PRE, Q2-POST*, and *Q3-PRE*) in the regression.

The sample consists of 68,497 observations for the period 1985–2004. For each firm-quarter, there has to be at least two analysts' forecasts of annual earnings within 45 days before the quarterly earnings announcement, and within 30 days after the announcement. Pre- and post-announcement are considered two different observations. If an analyst does not revise her forecast after the quarterly earnings announcement, then we assume she does not change her forecast. If an analyst makes multiple forecasts within a measurement window, then the one closest to the announcement date is used.

(continued on next page)

TABLE 4 (continued)

Variable Definitions:

DBF = Dispersion Bias Factor $\frac{STDMOD-STD}{STDMOD}$, where *STD* is standard deviation of analysts' forecast, *STDMOD* is standard deviation adjusted for the downward bias in *STD*, and the bias is calculated for every sample observation based on the ML estimation of the following model:

$$Log(STD_{it}) = \beta_0 + \beta_1 SIZE_{it} + \beta_2 BM_{it} + \beta_3 BETA_{it} + \beta_4 MOMENT_{it} + \beta_5 VAREPS_{it} + \beta_6 \Delta EPS_{it} + \beta_7 LOSS_{it} + \beta_8 RD_{it} + \beta_9 SDRES_{it} + \beta_{10} LOGNANALYST_{it} + \beta_{11} TURN_{it} + \beta_{12} DE_{it} + \beta_{13} SA_{it} + \beta_{14} LOG(ABSM)_{it} + \beta_{15} LOGP_{it} + v_{it} - u_{it};$$

HERDING INTENSITY = number of herding forecasts divided by the total number of forecasts for each firm-year. A herding forecast is a revised forecast that is between the existing consensus and the analyst's previous forecast;

CV(B_SIZE) = standard deviation of the size of the brokerage houses that employ analysts who release annual forecasts for a certain firm, divided by the mean size of the brokerage houses. Size of a brokerage house is measured by the number of analysts the brokerage house employed in a certain quarter;

CV(EXPERIENCE) = standard deviation of the analysts' tenure divided by the mean tenure of the analysts who release annual forecasts for a certain firm. An analyst's tenure is measured as how many days this analyst has been releasing annual earnings forecasts in the I/B/E/S database;

CV(TIMELINESS) = standard deviation of analysts' forecast timing, divided by the mean timing. Forecast timing is measured as the number of days between a forecast's release date and the quarterly earnings announcement date;

CV(ACCURACY) = standard deviation of forecast accuracy deciles, divided by the mean forecast accuracy deciles. An analyst's forecast accuracy is calculated based on her last year's average absolute forecast errors within an industry. The bigger the average forecast errors are, the lower the deciles she belongs to;

CV(FREQUENCY) = standard deviation of forecast frequency of the analysts who release annual forecasts for a certain firm, divided by the mean forecast frequency. An analyst's forecast frequency is calculated as the number of annual forecasts she released for a certain firm in a given year;

OPTIMISM = analysts' mean forecast minus earnings, scaled by stock price; and

DISTRESS = Zmijewski's (1984) Financial Distress Score.

Subsamples Where Observed Dispersion is Greater than Unmanaged Dispersion

As pointed out in the leader-follower analyst setup described in Appendix A, there could be situations in which analysts' strategic behavior may lead to observed dispersion exceeding the dispersion of unmanaged forecasts.[17] If this is the case, then it should be possible to fit the error model $\varepsilon = v + u$, rather than the model in Equation (2) which specifies $\varepsilon = v - u$, to parts of the sample where we expect observed dispersion to exceed dispersion of unmanaged forecasts.

---

[17] Bernhardt et al. (2006) examine the location of individual analyst forecasts relative to existing consensus and actual earnings and suggest that there is a 60 percent chance of an analyst at any particular point in time moving away from existing consensus. This result and our finding that, on average, dispersion of unmanaged forecasts is greater than observed dispersion are not necessarily contradictory. This is because of the following reasons: (1) observed dispersion is affected by not only whether analysts bias their forecasts away from or toward consensus, but also by how much; and (2) herding/anti-herding behavior is defined relative to *existing* consensus (which may itself be based on some biased past forecasts) in Bernhardt et al. (2006). This is different from the consensus based on unmanaged forecasts. In fact, it is easy to construct a number of examples where a majority of the analysts forecast away from existing consensus but the final observed dispersion is less than the dispersion of unmanaged forecasts. Consider for example a group of five analysts (A, B, C, D, and E) following a firm with unmanaged forecasts of 0.21, 0.22, 0.25, 0.29, and 0.3. Let E release her forecast first. Looking at the consensus of 0.3, analyst D moves her unbiased forecast away to, say, 0.26. Now the existing consensus is 0.28 ((0.3 + 0.26)/2). Let us say that B then issues her unbiased forecast of 0.22. The revised existing consensus is (0.3 + 0.26 + 0.22)/3 = 0.26. Let A then release her anti-herding forecast of 0.20 making the consensus (0.3 + 0.26 + 0.22 + 0.2)/4 = 0.245. Finally, C anti-herds and releases a forecast of 0.26 resulting in an observed forecasts vector of (0.2, 0.22, 0.26, 0.26, and 0.3). We have a case where three out of four follower analysts anti-herd and one analyst releases an unbiased forecast. But observed dispersion based on the managed forecasts is 0.039, whereas the dispersion based on the unmanaged forecasts is 0.040.

The cross-sectional distribution of the various determinants of the dispersion bias factor provides us with some guidance on the subsamples where upward dispersion bias is likely to be present. If a particular determinant has a positive (negative) association with the dispersion bias factor, then the bias is expected to be lower for relatively low (high) values of this variable. Therefore, subsamples characterized by low (high) values of this determinant are likely to have observed dispersion that is greater than dispersion of unmanaged forecasts. For example, given the significant positive association between dispersion bias and *HERDING INTENSITY*, we chose subsamples from the bottom 10, 25, and 50 percent of the overall sample when sorted by *HERDING INTENSITY* to check whether observed dispersion is greater than dispersion of unmanaged forecasts i.e., $\varepsilon = v + u$, in these samples. We found that in the 25 percent and 50 percent subsamples, the ML estimation yielded coefficients that were identical when compared to OLS coefficients and the estimated value of σ_u was indistinguishable from zero. In contrast, we were able to fit the $\varepsilon = v - u$ model for these two subsamples and the resulting σ_us were significant, confirming an on average downward dispersion bias.

However, in the subsample characterized by the bottom 10 percent of observations, when sorted based on *HERDING INTENSITY*, the ML procedure confirmed an, on average, *negative* dispersion bias factor. For this subsample, by construction, observed dispersion is greater than the estimated modified dispersion. For this 10 percent sample, the average value of the observed dispersion, modified dispersion and *DBF* respectively, were 0.069, 0.029 and −1.125. Not surprisingly, ML estimation for the subsample containing the remaining 90 percent of the observations provided results that were consistent with observed dispersion being less than the dispersion of unmanaged forecasts, with average value of the observed dispersion, modified dispersion and *DBF* at the level of 0.074, 0.142, and 0.561, respectively. We merged the two subsamples and compared the empirical distribution of the modified dispersion of the merged full sample with the corresponding distribution in Table 3, Panel A. The mean and the standard deviation of modified dispersion for the merged sample were 0.129 and 0.219 and these are very close to the original values of 0.133 and 0.220. The Pearson and Spearman correlations between the two distributions were also very high, 0.973 and 0.918, respectively, providing some evidence that the assumption of downward bias in observed dispersion for the full sample is a reasonable one despite the possibility that upward bias in observed dispersion may be present in parts of the sample.[18]

V. EMPIRICAL IMPLICATIONS

The preceding analysis provides empirical evidence that analysts' strategic behavior creates a downward bias in forecast dispersion. We have also demonstrated that observed dispersion can be adjusted upward on an observation-specific basis to generate a modified measure of dispersion that ostensibly estimates the dispersion that would have resulted if the analysts had not strategically managed their forecasts. In this section, we discuss specific research settings and empirically demonstrate where and how researchers can benefit from using our modified measure of dispersion.

Following Barron et al. (1998) a number of studies have used observed values of dispersion, variance of analysts' forecasts, (D), squared error in the mean forecast (SE), and the number of analysts (N) to estimate proxies for consensus, and public and private information precision, i.e.,:

---

[18] The ML procedure confirmed an on average, negative, dispersion bias factor in only one other subsample, characterized by the top 10 percent of observations when sorted by *CV(TIMELINESS)*. The dispersion bias factor was, on average, significantly positive for the remaining 90 percent of the full sample. Here again, the Pearson and Spearman correlations between the empirical distributions of modified dispersion were very high, 0.978 and 0.925, respectively.

$$CONSENSUS = \frac{SE - \frac{D}{N}}{\left(SE - \frac{D}{N}\right) + D};\ PUBLIC = \frac{SE - \frac{D}{N}}{\left[\left(SE - \frac{D}{N}\right) + D\right]^2};$$

$$\text{and } PRIVATE = \frac{D}{\left[\left(SE - \frac{D}{N}\right) + D\right]^2}.$$

Some studies (e.g., Barron et al. 2002) use these proxies, often referred to as BKLS measures, to examine the relative changes in public information quality and private information quality around events such as earnings announcements, while other studies (e.g., Botosan et al. 2004) exploit these measures to investigate the relative impact of the two different information sources (public versus private) on variables of interest such as cost of capital.

For given values of squared error in mean forecast (*SE*) and the number of analysts (*N*), it is straightforward to verify that both *CONSENSUS* and *PUBLIC* decrease when dispersion (*D*) increases. It is also the case that the partial derivative of *PRIVATE* with respect to *D* is positive whenever the squared error in mean forecast is greater than dispersion. Given the significant downward dispersion bias that we have documented earlier, these observations further suggest that the importance of public information relative to private information may have been overstated in prior studies.

Table 5 provides estimates of BKLS measures i.e., *CONSENSUS*, *PUBLIC*, and *PRIVATE* for a sample of 1,828 firms for which these variables can be calculated before and after the first, second, and third quarter earnings announcements.[19] Panel A shows the estimates when the observed dispersion measure is used and Panel B shows the estimates calculated with our bias-adjusted dispersion. Consistent with the above intuition we find significant reduction in the estimates of consensus, public information precision, and a significant increase in private information precision when our modified dispersion measure is used to replace the observed dispersion measure. Consider, for example, the forecast window following the third quarter earnings announcement (*Q3-POST*). The median *CONSENSUS*, *PUBLIC*, and *PRIVATE* measures in Panel A are 0.760, 50.168, and 17.430, respectively. The first two measures have significantly lower median values in Panel B, i.e., 0.412 and 15.211, and *PRIVATE* shows a significant increase to 25.654. A similar pattern is observed for all the other five forecast windows.

In addition, a number of striking differences emerge when Panels A and B of Table 5 results are compared. One of the main results in Barron et al. (2002), which is also confirmed by our results in Panel A, is that increases in *PUBLIC* around earnings announcements are greater than the increases in *PRIVATE*. In contrast, our results in the last column of Panel B based on the modified measure of dispersion suggest that *PRIVATE* increases around earnings announcements are significantly *greater* than increases in *PUBLIC*.[20] While both panels indicate that *CONSENSUS* continually decreases as one moves closer to the end of the year, the reduction in *CONSENSUS* is more than twice as much in Panel B, moving from 0.82 before first quarter announcement

---

[19] We only included those firm-years where all estimates of public information quality were positive since the theoretical development in BKLS always yields a positive consensus. We also repeated our analysis with an expanded sample where *PUBLIC* and the *CONSENSUS* were set to zero for cases where the estimated *PUBLIC* was negative. For these observations, *PRIVATE* was estimated as 1/*D*. Our inferences were similar in this expanded sample.

[20] Consider, for example, the increase in public information precision (10.307 − 8.949 = 1.358) and the increase in private information precision (0.774 − 0.459 = 0.315) around the first quarter earnings announcement in Panel A. Contrast these increases with the corresponding values (5.930 − 5.505 = 0.425) and (2.151 − 1.484 = 0.667) around the first quarter earnings announcement in Panel B.

TABLE 5

Consensus, Precision of Public Information, and Precision of Private Information around Interim Earnings Announcements

Panel A: *CONSENSUS*, *PUBLIC*, and *PRIVATE* Calculated using Observed Dispersion (n = 10,968)

[a] Wilcoxon signed ranks test of the null hypotheses that $\Delta CONSENSUS = 0$, $\Delta PUBLIC = 0$, and $\Delta PRIVATE = 0$.

[b] Wilcoxon signed ranks. We base tests on the statistic: $(\Delta PUBLIC - \Delta PRIVATE)$, the null hypothesis is that $(\Delta PUBLIC - \Delta PRIVATE) = 0$.

[c] Results indicate that $\Delta PUBLIC > \Delta PRIVATE$.

[d] Results indicate that $\Delta PUBLIC < \Delta PRIVATE$.

(continued on next page)

TABLE 5 (continued)

[e] Results indicate that $\Delta PUBLIC < 0$, i.e., precision of *public* information decreased after 3rd quarter's earnings announcement.

This table demonstrates how precision of public information (*PUBLIC*) and precision of private information (*PRIVATE*) contained in analysts' forecasts and the ratio of common-to-total information (*CONSENSUS*) change around interim earnings announcements throughout the year. In Panel A, *CONSENSUS*, *PUBLIC*, and *PRIVATE* are calculated based on observed analysts' forecasts dispersion, while in Panel B, they are calculated based on dispersion adjusted for analysts' strategic behavior. For both panels, forecast windows before earnings announcements run from day −45 through −1. Forecast windows after earnings announcements run from day 0 through 29, where day 0 is the Compustat quarterly earnings announcement date. This analysis requires each firm-year to have valid observations in all six windows (*Q1-PRE*, *Q1-POST*, *Q2-PRE*, *Q2-POST*, *Q3-PRE*, and *Q3-POST*). In the sample used, there are 1,828 firm-years, each having six observations, which lead to 10,968 observations overall.

Variable Definitions:

$CONSENSUS = \frac{SE - \frac{D}{N}}{(SE - \frac{D}{N}) + D}$, where $SE = (\text{mean forecasts} - \text{EPS})^2$, $N =$ number of analysts, $D = (STD)^2$, $STD =$ standard deviation of analysts' forecasts;

$PUBLIC = \frac{SE - \frac{D}{N}}{[(SE - \frac{D}{N}) + D]^2}$; and

$PRIVATE = \frac{D}{[(SE - \frac{D}{N}) + D]^2}$.

(*Q1-PRE*) to 0.41 after third quarter announcement (*Q3-POST*) when compared to corresponding results in Panel A (from 0.95 to 0.76). These results provide strong evidence that a significant reduction in consensus over time is caused by relatively substantial increases in quality of private information. This contrasts with the Panel A results that indicate significant increases in public information quality relative to modest increases in private information quality moderate the reduction in consensus. More generally, our results indicate that researchers investigating how changes in consensus, private, and public information around information events affect analysts' information-gathering activities should use our modified measure of dispersion in order to minimize the possibilities of drawing incorrect inferences.

The cross-sectional determinants of dispersion bias also provide some guidance on the types of firms for which measures of public and private information based on the observed dispersion will be more significantly biased toward public information. The cross-sectional results in Table 4, Panel B suggest that the difference between *CONSENSUS* derived from observed dispersion and its counterpart derived from our proposed dispersion measure will be significantly larger for those firms that have higher herding tendency (*HERDING INTENSITY*), higher variation in analyst experience (*CV*(*EXPERIENCE*)), higher variation in analyst capabilities (*CV*(*ACCURACY*)), higher levels of financial distress (*DISTRESS*), and higher levels of forecast optimism (*OPTIMISM*), and will be significantly lower in firms with higher levels of *CV*(*TIMELINESS*) and *CV*(*FREQUENCY*). To test these predictions, we regress the bias in *CONSENSUS* (estimated as the difference between consensus based on the observed dispersion measure and that based on the modified dispersion measure) on the above determinants of analysts' strategic behavior using a pooled cross-sectional regression with controls for time point of the year such as *Q1-PRE*, *Q1-POST*, etc., and the year. The regression results are presented in Table 6.

Consistent with the predictions, we find significant positive associations between the magnitude of upward bias in *CONSENSUS* and *HERDING INTENSITY*, *CV*(*ACCURACY*), *DISTRESS*, and *OPTIMISM*. In contrast to our predictions, we also observe a positive association between the bias in *CONSENSUS* and *CV*(*TIMELINESS*) *and CV*(*FREQUENCY*).[21] Overall, the regression results are consistent with public information quality being significantly overstated relative to private information quality when observed dispersion is used, particularly in firms with a greater degree of analyst strategic behavior.

Given the empirical evidence that private (public) information quality is understated (overstated), we next examine a research setting where the relative impact of public and private information precision plays a central role in research design. Botosan et al. (2004; hereafter, BPX) find that cost of equity capital is decreasing in consensus and increasing in the difference between a firm's private information precision rank and the firm's public information precision rank, a variable they label *RDIFF*. Combining the two results, BPX infer that cost of equity capital is decreasing in public information precision and increasing in private information precision. We examine whether these inferences are robust to how a change in the dispersion measure affects *CONSENSUS* and *RDIFF*. Table 7 provides the results of the following regression specification used in Table 5 of BPX. Specifically, we estimate:

$$\begin{aligned} \textit{Cost of equity capital} = {} & \theta_0 + \theta_1 BETA_{it} + \theta_2 GROW_{it} + \theta_3 LMKVL_{it} + \theta_4 BP_{it} \\ & + \theta_5 CONSENSUS_{it}\ (\text{or } RDIFF_{it}) + error_{it}, \end{aligned}$$

and provide the summary of nine annual cross-sectional regressions for the period from 1993 to

---

[21] It is possible that firms that have a high level of variability in forecast timeliness and frequency are also those with a significant quantity of liquidity trading. We speculate that these firms may be characterized by low consensus of opinion among traders and therefore a high level of estimation bias in the consensus measure.

TABLE 6

Cross-Sectional Determinants of the Bias in BKLS Consensus (n = 10,968)

	Predicted Sign	Estimated Coefficient	t-statistic	p-value
Intercept		0.173	16.98	< 0.001
HERDING INTENSITY	+	0.218	17.58	< 0.001
CV(EXPERIENCE)	+	0.001	0.71	0.868
CV(ACCURACY)	+	0.084	16.26	< 0.001
CV(B_SIZE)	+	0.006	1.21	0.228
CV(TIMELINESS)	−	0.013	4.24	< 0.001
CV(FREQUENCY)	−	0.055	6.39	< 0.001
DISTRESS	+	0.004	3.11	< 0.001
OPTIMISM	+	0.868	30.23	< 0.001
Year and Year-time Control		Yes		
Adjusted R^2		0.224		

This table shows the pooled-regression results of the following model:

$$\begin{aligned} CONSENSUS_{it} - CONSENSUSMOD_{it} = {} & \delta_0 + \delta_1 HERDING\ INTENSITY_{i,t} + \delta_2 CV(EXPERIENCE)_{i,t} \\ & + \delta_3 CV(ACCURACY)_{i,t} + \delta_4 CV(B\_SIZE)_{i,t} + \delta_5 CV(TIMELINESS)_{i,t} \\ & + \delta_6 CV(FREQUENCY)_{i,t} + \delta_7 DISTRESS_{i,t} + \delta_8 OPTIMISM_{i,t} \\ & + error_{i,t}. \end{aligned}$$

We use the fractional rank for all the independent variables. We also include year dummy and year-time dummy (*Q1-PRE*, *Q1-POST*, *Q2-PRE*, *Q2-POST*, and *Q3-PRE*) in the regression.

In the sample used, forecast windows before earnings announcements run from day −45 through −1. Forecast windows after earnings announcements run from day 0 through 29, where day 0 is the Compustat quarterly earnings announcement date. We require each firm-year to have valid observations in all six windows (*Q1-PRE*, *Q1-POST*, *Q2-PRE*, *Q2-POST*, *Q3-PRE*, and *Q3-POST*). There are 1,828 firm-years, each having six observations, which lead to 10,968 observations over all.

Variable Definitions:

$CONSENSUS = \frac{SE - \frac{D}{N}}{\left(SE - \frac{D}{N}\right) + D}$, where $SE = (\text{mean forecasts} - EPS)^2$, N = number of analysts, $D = (STD)^2$, STD = standard deviation of analysts' forecasts;

$CONSENSUSMOD = \frac{SE - \frac{DMOD}{N}}{\left(SE - \frac{DMOD}{N}\right) + DMOD}$, where $DMOD = (STDMOD)^2$, *STDMOD* is the standard deviation adjusted for the downward bias in *STD*, where the bias is calculated for every sample observation based on the ML estimation of the following model:

$$\begin{aligned} Log(STD_{it}) = {} & \beta_0 + \beta_1 SIZE_{it} + \beta_2 BM_{it} + \beta_3 BETA_{it} + \beta_4 MOMENT_{it} + \beta_5 VAREPS_{it} + \beta_6 \Delta EPS_{it} + \beta_7 LOSS_{it} \\ & + \beta_8 RD_{it} + \beta_9 SDRES_{it} + \beta_{10} LOGNANALYST_{it} + \beta_{11} TURN_{it} + \beta_{12} DE_{it} + \beta_{13} SA_{it} \\ & + \beta_{14} LOG(ABSM)_{it} + \beta_{15} LOGP_{it} + v_{it} - u_{it}; \end{aligned}$$

HERDING INTENSITY = number of herding forecasts divided by the total number of forecasts for each firm-year. A herding forecast is a revised forecast that is between the existing consensus and the analyst's previous forecast;

CV(B_SIZE) = standard deviation of the size of the brokerage houses that employ analysts who release annual forecast for a certain firm, divided by the mean size of the brokerage houses. Size of a brokerage house is measured by the number of analysts the brokerage house employed in a certain quarter;

CV(EXPERIENCE) = standard deviation of the analysts' tenure divided by the mean tenure of the analysts who release annual forecasts for a certain firm. An analyst's tenure is measured as how many days this analyst has been releasing annual earnings forecasts in the I/B/E/S database;

CV(TIMELINESS) = standard deviation of analysts' forecast timing, divided by the mean timing. Forecast timing is measured as the number of days between a forecast's release date and the quarterly earnings announcement date;

(continued on next page)

TABLE 6 (continued)

CV(ACCURACY) = standard deviation of forecast accuracy deciles, divided by the mean forecast accuracy deciles. An analyst's forecast accuracy is calculated based on her last year's average absolute forecast errors within an industry. The bigger the average forecast errors are, the lower the deciles she belongs to;
CV(FREQUENCY) = standard deviation of forecast frequency of the analysts who release annual forecast for a certain firm, divided by the mean forecast frequency. An analyst's forecast frequency is calculated as the number of annual forecasts she released for a certain firm in a given year;
OPTIMISM = analysts' mean forecast minus earnings, scaled by stock price; and
DISTRESS = Zmijewski's (1984) Financial Distress Score.

2001. Table 7, Panels A and B, respectively, present the results when *CONSENSUS* and *RDIFF* are calculated using observed and modified dispersion measures. As can be seen from Panel B, the negative association between cost of capital and consensus continues to hold when consensus is derived from the modified dispersion measure. However, the association between cost of capital and *RDIFF* reverses sign from positive in Panel A to significantly *negative* in Panel B when our modified dispersion measure is used to estimate public and private information precision. The sign-reversal on *RDIFF* is also observed when both *CONSENSUS* and *RDIFF* are included in the regression specification. The regression coefficients on the *CONSENSUS* and *RDIFF* in Panel B suggest that *both* relatively high levels of public information precision and relatively high levels of private information precision are associated with lower levels of information asymmetry and, therefore, a lower cost of equity capital. Interestingly, this empirical non-monotonic relationship between public information quality and information asymmetry is consistent with theoretical results of endogenous information acquisition described in Kim and Verrecchia (1991).[22]

Studies that Use Dispersion as an Independent Variable

Our empirical results, which indicate that there is a downward bias in dispersion and that the modified dispersion measure has a higher cross-sectional variation than observed dispersion, also have crucial implications for research designs where dispersion features as an important independent variable and observed dispersion are used as a proxy for the dispersion construct.[23] Specifically, one cannot appeal to the standard result from the classical errors-in-variable approach that measurement error in an independent variable biases its regression coefficient toward zero. This is because the measurement error in dispersion has a *negative* correlation with the underlying construct.[24]

Maddala (2001, 459) shows that in the correlated-errors-in-variable situations, the covariance between the true measure and measurement error has a significant influence on the nature and magnitude of the bias in the regression coefficient. When negative correlated error is present, three

---

[22] Kim and Verrecchia (1991) show that information asymmetry increases as the precision of an anticipated public announcement increases up to some point, and steadily decreases thereafter (that is, its behavior is unimodal, Proposition 2 [Kim and Verrecchia 1991, 286]).

[23] We observe that the variance of observed dispersion is smaller than variance of our modified dispersion measure not only in our full sample, but also in subsamples of small and large firms, early and late sample period observations, as well as early in the year observations and late in the year observations.

[24] This is because, *variance of observed dispersion* = *variance of dispersion* + *variance of error* + 2 *times the covariance between dispersion and error*. The first two terms on the right-hand side are strictly positive; therefore, it is necessary that the covariance between dispersion and error be negative for observed dispersion to have a lower variance than dispersion.

TABLE 7

Multivariate Tests of the Association between Cost of Equity Capital and Relative Information Quality Measures

Panel A: *CONSENSUS* and *RDIFF* Calculated Using Observed Dispersion (n = 10,789)

Dependent Variable = Cost of Equity Capital

In both Panel A and Panel B, each row is a summary of nine annual cross-sectional regressions from 1993–2001. The reported coefficients are the mean coefficients. The t-statistics are based on the standard error of the coefficient estimates across the nine years, adjusted for auto-correlation in the annual coefficients based on an assumed AR1 autocorrelation structure. The sample contains 10,789 firm-year observations, ranging from 849 firms in 1993 to 1,431 firms in 1999. In Panel A both *CONSENSUS* and *RDIFF* are calculated using observed dispersion, while in Panel B they are calculated based on dispersion adjusted for analysts' strategic behavior.

Variable Definitions:

$Cost\ of\ Equity\ Capital = A + \sqrt{A^2 + \frac{EPS_1}{P_0}\left[\frac{1}{2}\left(\frac{EPS_2 - EPS_1}{EPS_1} + \frac{EPS_5 - EPS_4}{EPS_4}\right) - (r_f - 0.03)\right]}$ (based on a valuation model originating from Ohlson and Juettner-Nauroth [2005] and estimated as in Gode and Mohanram [2003]) where EPS_i is analysts' earnings forecasts for the *i*th year in the future, P_0 is the closing price for the estimated period, and $A = \frac{1}{2}\left[(r_f - 0.03) + \frac{dps_1}{P_0}\right]$, dps_1 = forecasted dividend per share, r_f = yield on ten-year notes;

BETA = beta estimated using a market model with a minimum of 30 monthly returns over the 60 months prior to June 30th of the year expected cost of capital is estimated;

GROW = I/B/E/S forecasts of long-range (three to five years) earnings growth;

LMKVL = natural log of the market value of equity;

BP = book value of common equity divided by the market value of common equity;

$CONSENSUS = \frac{SE - \frac{D}{N}}{\left(SE - \frac{D}{N}\right) + D}$, where $SE = (\text{mean forecasts} - EPS)^2$, N = number of analysts, $D = (STD)^2$, STD = standard deviation of analysts' forecasts; and

RDIFF = *RPRIVATE* − *RPUBLIC*, where *RPRIVATE* is the fractional rank of *PRIVATE*, *RPUBLIC* is the fractional rank of *PUBLIC*, and $PUBLIC = \frac{SE - \frac{D}{N}}{\left[\left(SE - \frac{D}{N}\right) + D\right]^2}$, $PRIVATE = \frac{D}{\left[\left(SE - \frac{D}{N}\right) + D\right]^2}$.

mutually exclusive cases are possible: (1) sign-reversal: the observed and true regression coefficients have *opposite* signs, (2) amplification: the coefficients have the same sign and the observed coefficient is biased away from zero, and (3) attenuation: the coefficients have the same sign and the observed coefficient is biased toward zero.

The above discussion provides guidance about specific situations where the use of our modified measure of dispersion is warranted. First, the fact that sign-reversal is a possibility has implications for studies that develop and test competing hypotheses about the predicted association between a variable of interest and dispersion. It is important for these studies to necessarily verify that empirical evidence in support of one of the two competing hypotheses, when observed dispersion is used as a proxy, is not overturned in favor of the alternative hypothesis when the modified dispersion measure suggested in this paper is used.[25] Second, the amplification effect, if present, may be problematic for those studies where the observed magnitude of the regression coefficient plays a key role in interpreting the findings. The smaller coefficient on the modified dispersion measure may more accurately reflect the true magnitude of the association in these cases. Finally, the attenuation effect, when present, may lead researchers to not reject the null hypothesis of no relationship between dispersion and the variable of interest; these researchers can perform more powerful tests by using the modified dispersion measure because it would more likely capture the true relationship if that exists.

VI. SUMMARY AND CONCLUSIONS

We analyze the cross-sectional determinants of forecast dispersion and provide large-sample evidence that in addition to being significantly associated with proxies for fundamental risk, uncertainty, and divergence of beliefs, forecast dispersion also suffers from a downward bias. We interpret our evidence as suggesting that observed dispersion is affected by analysts' strategic behavior and, on average, understates the dispersion of unmanaged forecasts.

We also provide a method to quantify the downward bias at the firm-quarter level and find that, on average, the observed dispersion understates the dispersion of unmanaged forecasts by 53.4 percent. There is also considerable cross-sectional variation in the effect of strategic behavior on forecast dispersion with important implications for studies that employ dispersion-based proxies of analysts' information environments. Specifically, we show that the relative magnitude of private information quality is significantly understated relative to public information quality, providing potentially incorrect inferences concerning analysts'' information-gathering activities around information events such as earnings announcements.

The estimation procedure that we suggest has been in use in the production economics literature for more than three decades. The availability of Maximum Likelihood (ML) estimation routines in almost all statistical packages facilitates implementation of the estimation procedure in large samples of financial data as we have illustrated. While it is impossible to observe and document analysts' actual beliefs and the associated dispersion of these beliefs, we argue that our modified measure of dispersion is a more precise measure of the underlying dispersion of analysts' actual beliefs. The various empirical demonstrations that we provide lend further credibility to this belief.

---

[25] For example, Güntay and Hackbarth (2010) examine the association between corporate bond credit spreads and forecast dispersion by developing two competing hypotheses. The first hypothesis views dispersion as a measure of divergence of opinion and argues that higher forecast dispersion leads to higher firm values and, hence, lower credit spreads. The second hypothesis contends that forecast dispersion proxies for future cash flow uncertainty and, therefore, higher forecast dispersion leads to higher credit spreads. Güntay and Hackbarth (2010) find support for the second hypothesis.

APPENDIX A

Demonstration of Dispersion Bias

Suppose there are three analysts A, B, and C, following a specific firm. Let F_A, F_B, and F_C, respectively, be their unmanaged forecasts. Assume $F_A < F_B < F_C$. Assume that one of these three analysts has more expertise than the others and is perceived by the other two (and herself) as the "leader." The leader releases her forecast first and one or both of the other analysts simply copy the leader even if the leader's forecast is inconsistent with their information. The following table shows 9 different scenarios for the above setup, and illustrates how this type of analyst behavior influences forecast dispersion and mean forecast.

Follower	Leader	Dispersion	Mean Forecast
A	B	↓	↑
A	C	↓	↑
B	A	↑	↓
B	C	↑	↑
C	A	↓	↓
C	B	↓	↓
AB	C	↓	↑
BC	A	↓	↓
AC	B	↓	ambiguous

CEO Pay, Managerial Power, and SFAS 123(R)

Terrance R. Skantz
The University of Texas at Arlington

ABSTRACT: This study presents evidence that option expensing, whether voluntary under SFAS 123 or mandatory under SFAS 123(R), is associated with changes in CEO compensation that are beneficial to shareholders. I find that the reporting benefits of aggregate-employee option grants under SFAS 123 are associated with the change in the mix of CEO option grants and stock grants that occurs after SFAS 123(R), suggesting that reporting benefits of option grants may have influenced some CEO compensation decisions. Additionally, I find that the reduction in CEO pay after SFAS 123(R) is greater when shareholders have more power to act in their own best interest and when there is evidence of pre-expensing CEO compensation rents. The findings suggest that SFAS 123 may have encouraged inefficient, CEO-preferential pay practices and that SFAS 123(R) may have contributed to a reduction in CEO compensation inefficiencies.

Keywords: *stock option grants; CEO; compensation; management entrenchment; pay-for-luck; SFAS 123(R).*

Data Availability: *All data are publicly available.*

I. INTRODUCTION

For annual reporting periods beginning after June 15, 2005, SFAS 123(R) (FASB 2004) requires firms to recognize employee stock option grants as compensation expense and prohibits the alternative practice of footnote-only disclosure of *pro forma* net income effects that SFAS 123 had previously permitted. Consistent with prior research, this study shows that the switch to income statement recognition is associated with changes in all components of CEO pay. Whether those changes in CEO compensation are improvements for shareholders remains an open question. I provide some evidence that they are. Using a sample of voluntary and involuntary option

expensing firms, I find that the changes in CEO compensation after the implementation of SFAS 123(R) are consistent with a reduction in inefficient contracting and rent extraction.[1]

Relying on the perceived cost hypothesis (Murphy 2002), this study first examines whether a measure of the "reporting benefits" of employee option grants under SFAS 123 is associated with changes in CEO compensation that occur after the adoption of option expensing. I define reporting benefits as the incremental return on equity due to the compensation expense that a firm avoided from option grants to all employees as a group *vis-à-vis* alternative forms of compensation that would have been expensed under SFAS 123. Reporting benefits is a proxy for the importance of financial reporting considerations in compensation decisions under SFAS 123. If financial reporting considerations did not influence CEO compensation decisions under SFAS 123, then I would expect reporting benefits of option grants in the pre-expensing period to be independent of the changes in CEO pay components that occur after firms begin to expense options.

In the period before options were expensed, I find that there is a higher rate of growth in CEO option grants and lower rate of growth in restricted stock grants when the reporting benefits of option grants is larger, consistent with Carter et al. (2007), who find an increasing preference for option grants over stock grants as reporting concerns increase. I also find that the rate of growth in CEO option grants decreases and that the rate of growth in restricted stock grants increases after the implementation of SFAS 123(R), consistent with the perceived cost hypothesis and several prior studies. Further, I find that the changes in both growth rates are more pronounced when the reporting benefits of option grants under SFAS 123 is larger. It is unlikely that the association between reporting benefits and CEO option and stock grants is mechanical because reporting benefits is based on option grants to all employees as a group and not just grants to the CEO. The findings suggest that, if reporting considerations were sufficiently important, some firms may have relied more on CEO option compensation and less on CEO restricted stock compensation under SFAS 123 than if both forms of compensation were expensed. The results also imply that some firms may have sacrificed CEO incentive considerations in exchange for the financial statement reporting benefits of CEO option grants under SFAS 123 and, further, that those compensation inefficiencies diminished after SFAS 123(R) eliminated the financial reporting advantage of option compensation.

A second set of tests relies on the theory of managerial power and examines whether the reduction in CEO compensation that occurs after the implementation of SFAS 123(R) is consistent with a curtailment of CEO compensation rents. As a proxy for managerial power, I use a measure of management entrenchment (Bebchuk et al. 2009). Entrenched managers are difficult to remove from office and can influence the pay process to their advantage (Bebchuk et al. 2009; Bebchuk and Fried 2003). Under managerial power theory, entrenched CEOs are likely to have avoided some or all of the reduction in CEO compensation rents that may have occurred after firms began to expense options. Stated alternatively, if SFAS 123(R) increased reporting transparency and revealed CEO compensation rents that were previously obscured by SFAS 123, the reduction in CEO compensation that occurs after the implementation of SFAS 123(R) should be more pronounced, *ceteris paribus*, when shareholders have more power to remove the CEO and to reshape CEO compensation in the shareholders' interest. Under the premise that shareholders are rational and the CEO labor market is competitive, shareholders would not reduce CEO compensation unless they believe that CEO compensation rents exist for fear of losing the CEO to another firm. I find that the post-expensing reductions in the rates of growth in option compensation, equity compensation, and total compensation are larger for less entrenched CEOs who, compared to their more entrenched counterparts, are less able to resist changes in compensation that are beneficial to shareholders but not the CEO. The findings are consistent with a reduction in CEO compensation rents after the implementation of option expensing.

---

[1] I use "SFAS 123(R)" to refer to option expensing and "SFAS 123" to refer to footnote-only disclosure of *pro forma* net income effects of implied option compensation, for both voluntary and involuntary expensing firms.

In a final series of tests, I use the sensitivity of CEO pay to strong sector performance in the SFAS 123 period as a proxy for rent extraction and examine how that proxy is associated with CEO compensation under SFAS 123 and with changes in CEO compensation following the implementation of SFAS 123(R). Following Albuquerque (2009), I use industry-size peer group stock returns to measure sector performance. When firms link CEO compensation to good *sector* performance, CEOs are in effect rewarded for good luck because sector performance represents the contribution that exogenous shocks made to firm performance rather than the contribution that the CEO made to firm performance. Rewarding CEOs for good sector performance will provide them with excess compensation (Bertrand and Mullainathan 2001) unless there are offsetting cuts to CEO compensation elsewhere. Agency theory would predict that firms would reward a CEO for performance relative to that of other firms in the same sector and, hence, not reward the CEO simply for strong sector performance.

I first estimate separately for each firm a measure of "pay for good luck" during the SFAS 123 period. Pay for good luck is equal to the sensitivity of CEO compensation to good sector performance relative to the sensitivity of CEO pay to firm performance net of sector performance. Pay for good luck is positive for more than 50 percent of the firms in my sample, indicating that, for most firms, CEO pay was more sensitive to good sector performance (i.e., good luck) under SFAS 123 than to firm performance net of sector performance (i.e., the CEO's contribution). I find that CEOs with above-average pay for good luck experience higher rates of growth in compensation in the pre-expensing period for the pay component of cash, options, stock, and total compensation compared to other CEOs. This result is expected if pay for good luck is associated with excessive CEO pay. Additionally, those same CEOs experience greater reductions in the rates of growth in cash, option, and total compensation and a smaller increase in the rate of growth in restricted stock compensation compared to other CEOs after their firms begin to expense options. The results are consistent with a reduction in compensation rents after the implementation of SFAS 123(R). In summary, the findings in this study suggest that the changes in CEO compensation that occurred after the implementation of SFAS 123(R) are beneficial to shareholders.

II. THIS STUDY'S CONTRIBUTION TO EXISTING RESEARCH

For a sample of firms that were among the first to voluntarily expense option grants beginning in 2002 or 2003, Carter et al. (2007) find a larger decrease in option grants and a larger increase in restricted stock grants after they begin to expense options compared to firms that did not expense options, consistent with my findings in this respect. However, the authors find no difference in the change in total CEO compensation between the two groups of firms and conclude that "firms find it difficult to downsize the large executive pay packages that resulted from the favorable accounting treatment for stock options" (Carter et al. 2007, 329). In contrast, using a model that controls for calendar-year trend effects and other factors expected to affect CEO compensation, I do find a statistically significant reduction in the rate of growth in total CEO pay after firms began to expense option grants for a sample of firms that generally were late to expense options, some voluntarily under SFAS 123 and most involuntarily under SFAS 123(R). The difference between my findings and Carter et al. (2007) may reflect the increasing public criticism of lofty CEO pay levels, systematic differences between voluntary and involuntary expensing firms, or both.

Previous studies examine how financial reporting concerns are associated with option compensation *prior to* option expensing (Matsunaga 1995; Core and Guay 1999; Carter et al. 2007) and how financial reporting concerns and corporate governance are associated with changes in executive compensation in *anticipation of* option expensing (Brown and Lee 2007). For the decade between 1979 and 1989, Matsunaga (1995) shows that option grants are greater when income is below a target income level than when it is above the target level and also when a firm uses a relatively high proportion of income-increasing accounting methods. Carter et al. (2007) show that firms with reporting concerns and with plans to access capital markets from 1995 to 2001 are more likely to grant options to CEOs. Brown and Lee (2007) find that the proportion of compensation paid in stock options to the top five executives decreased in 2005 in anticipation of SFAS 123(R) and that the reduction in option grants is larger for firms with financial reporting concerns and weak governance.

Building on previous studies that document that the reporting advantage of option grants influenced compensation decisions, this paper makes several contributions to the literature. First, my analysis considers all CEO pay components, individually and in the aggregate, which is vital because firms should adjust pay components jointly rather than individually. Previous research has focused primarily, although not exclusively, on option and restricted stock grants. Second, my sample includes voluntary and involuntary expensing firms. In contrast, Carter et al. (2007) consider only voluntary expensing firms, and Brown and Lee (2007) exclude early voluntary expensing firms. Third, my research design captures the full effect of option expensing on CEO pay, including changes from the year immediately prior to option expensing through the first two implementation years. By comparison, the changes in compensation in Brown and Lee (2007) include only changes in anticipation of option expensing. Fourth, I examine how management entrenchment and pay for good luck are associated with changes in CEO compensation around the change in accounting standards for stock options. The results for entrenchment and pay for good luck, which the option expensing literature has not examined previously, provide strong support for the assertion that SFAS 123(R) reduces CEO compensation rents.

This study also adds to what we know from Brown and Lee (2010), who find that CEO option grants are lower in the post-Enron period (2002–2006) than in the pre-Enron period (1998–2001). As noted by Brown and Lee (2010), the post-Enron period saw significant regulatory changes, a renewed public focus on executive compensation, and the issuance of SFAS 123(R), all of which are likely to have influenced the post-Enron changes in CEO compensation that they document. By comparison, more than 80 percent of my sample first expensed options in fiscal year 2006, the last possible period for option expensing. As a result, the benchmark compensation for the majority of my sample in fiscal years 2003 and 2004 already reflects Enron effects. Moreover, inferences in this paper are unchanged when I restrict the sample to firms that expensed involuntarily (not tabulated). Thus, the changes in CEO compensation documented in this study appear to be reasonably interpreted as primarily the effect of option expensing *per se*, i.e., as changes in CEO pay practices that occur after the implementation of SFAS 123(R) and that are incremental to the changes in CEO compensation that occurred after other regulatory changes and changes in public sentiment about CEO pay levels.

III. HYPOTHESES

Reporting Benefits of Option Grants and CEO Compensation

The perceived cost hypothesis (Murphy 2002) predicts that if option grants are not charged against reported earnings, then some companies will favor option grants over other forms of compensation. Hall and Murphy (2003) argue that the absence of a reported expense for stock option grants under SFAS 123 (and earlier under APB 25) helped fuel the growth in option compensation during the 1990s and early 2000s. Studies that are consistent with the perceived cost hypothesis include those that document larger option grants in the presence of financial reporting concerns under SFAS 123 (Brown and Lee 2007; Carter et al. 2007; Matsunaga 1995) and those that conclude that some firms accelerated the vesting date of previously issued employee stock options to avoid option-related compensation expense that otherwise would have been recognized under SFAS 123(R) (Balsam et al. 2008; Choudhary et al. 2009).

Several studies conclude that option grants were undervalued under SFAS 123, thus disguising the actual amount of employee compensation. Yermack (1998) estimates that *Fortune* 500 firms undervalued CEO options by an average of 8.9 percent. Aboody et al. (2006) and Bartov et al. (2007) find that firms used their discretion over option-pricing model inputs to understate option values. Collectively, these studies conclude that the understatement of option values is greater when CEO compensation is excessive, when implied option compensation expense is higher, and when there are incentives to understate compensation. Similarly, Balsam et al. (2008) find that accelerated vesting in advance of SFAS 123(R) is more likely when the avoided expense is higher. Hodder et al. (2006, 967) conclude that firms that understate option values "have incentives to manage earnings and to disguise the size and value of compensation packages."

In summary, prior research suggests that some firms may have believed they could disguise the economic cost of employee compensation by favoring option grants over other forms of compensation under SFAS 123, by accelerating option vesting dates, and by understating the value of option compensation. The latter practice is consistent with Libby et al. (2006) who find that audit partners may be more willing to tolerate misstatements of option compensation when it is disclosed in the footnotes rather than recognized in the financial statements.

From the perspective of reported earnings, an option grant had no marginal cost under SFAS 123. Thus, from a strict earnings perspective, an option grant could be justified even if no favorable incentive effects were expected. As concerns about the level of reported income became more important, a firm had an increasing incentive to substitute option grants for other forms of compensation. By contrast, under SFAS 123(R), reported earnings reflect the incentive effects of option grants and also their cost. Accordingly, earnings-focused compensation committees would be expected to reconsider their compensation practices after SFAS 123(R).

This study uses implied, aggregate-employee option compensation expense in the pre-expensing period, scaled by market value of equity (Aboody et al. 2004), as a proxy for the importance of reported income effects for compensation decisions in the pre-expensing period. Prior research suggests that the reporting benefits of option grants under SFAS 123, as measured in this study, correlates with an assortment of corporate governance deficiencies and earnings management incentives (debt covenant constraints, earnings shortfalls, capital market access, etc.). Thus, my measure of reporting benefits parsimoniously encapsulates the net effect of the opportunities and incentives to manage reported earnings and to understate compensation expense through option grants under SFAS 123.

Building on the perceived cost hypothesis, this study's first hypothesis predicts that firms with larger reporting benefits under SFAS 123 will have a greater decrease in the rate of growth in CEO option grants and a greater increase in the rate of growth in CEO stock grants after SFAS 123(R) than firms with smaller reporting benefits. This prediction is based on prior evidence that firms with reporting concerns preferred option grants to restricted stock grants when option grants were not expensed. The first hypothesis also predicts that firms with larger reporting benefits under SFAS 123 will have larger post-expensing reductions in the rate of growth in total CEO pay than firms with smaller reporting benefits. This second prediction is based on prior evidence that the absence of financial statement recognition of option compensation may have encouraged excessive CEO compensation and, further, that any CEO pay component can be responsible for excessive compensation. For example, firms could have designed option grants to the CEO optimally under SFAS 123 and chosen to pay excess compensation in the form of salary and bonus. The absence of compensation expense for option compensation, especially in conjunction with understatement of the implied option compensation expense in SFAS 123 disclosures, could have partially or fully concealed excess compensation. It is unlikely that any association between reporting benefits of option grants under SFAS 123 and changes in CEO compensation after the implementation of SFAS 123(R) is a simple mechanical effect because reporting benefits of options grants is based on option grants to all employees and not option grants to the CEO alone.

H1: The greater a firm's reporting benefits from aggregate-employee option grants under SFAS 123, the greater will be the firm's reduction in the rate of growth in CEO option pay and CEO total pay and the greater will be the firm's increase in rate of growth in CEO restricted stock compensation after the adoption of SFAS 123(R).

Managerial Power and CEO Compensation

Bebchuk and Fried (2003) argue that powerful managers can often influence the compensation process to their advantage. I use the construct "CEO entrenchment" and the related E-index (Bebchuk et al. 2009) to capture managerial power. The E-index is a function of six corporate governance provisions that limit shareholder power to replace management: staggered boards with overlapping terms, shareholder limits on amending corporate bylaws, shareholder limits on amending corporate charters, supermajority approval of mergers, golden parachutes, and poison pills. Bebchuk et al. (2009) show that firms with higher values of the E-index, which indicates more deeply entrenched managers, are more likely to have significantly lower future abnormal returns than firms with less entrenched managers.

I argue that more entrenched CEOs are more likely than other CEOs to successfully lobby their compensation committees for excess compensation. Entrenched managers are difficult to remove from office. Thus, they have a relatively low likelihood of forfeiting any compensation rents and a correspondingly high expected return on lobbying efforts. By not requiring the cost of options to be expensed, SFAS 123 is also very likely to have facilitated executive lobbying for greater option compensation to conceal rent extraction (Bebchuk and Fried 2004; Yermack 1998; Aboody et al. 2006; Hodder et al. 2006; Bartov et al. 2007).

The second hypothesis makes two predictions that, if confirmed, are consistent with rent extraction under SFAS 123 and with subsequent improvements in compensation efficiency under SFAS 123(R). First, in the pre-expensing period, I expect more entrenched CEOs to experience higher rates of growth in both option compensation and total compensation than less entrenched CEOs. Second, because more entrenched CEOs face fewer consequences from the increase in transparency that accompanies the adoption of option expensing, I expect more entrenched CEOs to experience smaller reductions in rates of growth in both option compensation and total compensation than less entrenched CEOs after the implementation of SFAS 123(R).

H2: More entrenched CEOs will have higher rates of growth in option and total compensation in the pre-expensing period and smaller reductions in rates of growth in option and total compensation after the adoption of SFAS 123(R) than less entrenched CEOs.

Sensitivity to Sector Performance and CEO Compensation

When an agent's effort level is not observable and when peer group or sector performance is correlated with firm performance, a second-best compensation contract will rely on observable outcome measures and some form of relative performance evaluation (Holmström 1982). Relative performance evaluation removes the effect of exogenous factors (i.e., good and bad luck) from the observable performance measure and provides a residual measure of performance that captures an agent's contribution (Lambert 2001). For example, when firm performance is adjusted for sector performance, the portion of firm earnings related to sector-wide losses (gains) is added to (deducted from) firm-level earnings. Therefore, relative performance evaluation adjusts CEO performance measures to remove the effect of factors beyond the control of the CEO, shields CEO compensation from the effects of sector gains and losses, and tightens the link between compensation and a CEO's contribution to firm performance. Based on proxy statement disclosures required since 2006, Gong et al. (2011) find that 27 percent of S&P 1500 firms explicitly acknowledge that they use relative performance evaluation in executive compensation. In practice, it is unlikely that firms can identify performance measures that are completely free of the effects of exogenous factors. Nevertheless, relative performance evaluation should mitigate the effect that exogenous factors (luck) would otherwise have on CEO compensation.

Bertrand and Mullainathan (2001) conclude that CEOs are rewarded as much for luck as for skill. Likewise, and consistent with CEO pay for luck, Albuquerque (2009) reports that several broad-based archival studies find that CEO compensation is based on, rather than shielded from, the effects of sector performance. Garvey and Milbourn (2006) argue, however, that a manager has relatively little incentive to seek *symmetric* rewards for luck. Instead, a manager will benefit from a reward structure that pays the manager more when the firm experiences good luck and yet shields the manager's compensation from the effects of bad luck. Asymmetric pay for luck leads to higher expected compensation with less downside risk for the manager. Garvey and Milbourn (2006) report evidence that penalties for bad luck are significantly smaller than rewards for good luck, consistent with pay-for-luck asymmetry that favors the CEO.

Albuquerque (2009) argues that previously documented pay for luck may reflect poorly chosen peer-group indices rather than an absence of relative performance evaluation. Using cross-sectional regression models with peer-group performance benchmarks based on a firm's industry classification and size quartile, Albuquerque (2009) finds evidence that CEO compensation is shielded from the effects of luck, at least partially, consistent with relative performance evaluation. Similarly, I also find support for relative performance evaluation for my sample in cross-sectional analyses with industry-size market-return benchmarks (details available upon request). The use of industry-size performance benchmarks, rather than the typical industry-alone benchmarks, is based on the observation that larger firms have more strategic flexibility, fewer financial constraints, greater diversification (Albuquerque 2009), and more talented CEOs (Gabaix and Landier 2008). In short, industry-size performance benchmarks parsimoniously reflect factors that are relevant to CEO performance benchmarking (Goplan et al. 2009; Rajgopal et al. 2006; Oyer 2004) but that are not reflected in performance benchmarks based on industry classification alone.

As described in detail later, I use the results of firm-specific time-series compensation regressions to sort firms by the sensitivity of CEO pay to good sector performance under SFAS 123. Following Albuquerque (2009), I assume that industry-size market returns are appropriate relative performance evaluation benchmarks and thus use those benchmarks as measures of good (and bad) sector performance in my firm-specific regression models. I find significant variation in the sensitivity of CEO pay to good sector performance (good luck) across the sample, with some firms rewarding CEOs for good luck and others shielding, partially or completely, CEO compensation from the effects of good luck. Although evidence from cross-sectional regression models with industry-size benchmarks suggests that CEO compensation is shielded from the effects of good and bad luck *on average* (Albuquerque 2009), that evidence does not preclude the significant variation in pay for luck that is indicated by the results of my firm-specific models.

My third hypothesis examines whether compensation rents were present under SFAS 123 and whether those rents are smaller under SFAS 123(R). I use the sensitivity of CEO pay to good luck under SFAS 123 as a proxy for potential rent extraction. Good and bad luck are defined, respectively, as positive and negative industry-level stock returns for a firm's industry classification and size quartile. Luck represents that portion of a firm's stock return that is due to systematic factors beyond the control of the CEO. The sensitivity of CEO pay to luck in my model in Section IV is negative when a firm uses relative performance evaluation to at least partially remove the contribution that luck made to firm performance, and greater than or equal to zero when a firm compensates luck as much as or more than a CEO's individual contribution to firm performance. As the sensitivity of CEO pay to good luck increases, *ceteris paribus*, CEO pay increases and, after some point, the CEO pay structure becomes inconsistent with relative performance evaluation. As described fully in Section IV, I use the sensitivity of CEO pay to good luck under SFAS 123 to classify CEOs by potential rent extraction.

While both pay for good luck and pay for bad luck are inefficient pay practices, I do not use the sensitivity of CEO pay to bad luck to classify CEOs by potential rent extraction. When sector performance is negative, a pay structure that is *consistent* with relative performance evaluation will result in higher CEO compensation than a pay structure that is *inconsistent* with relative performance evaluation, *ceteris paribus*. Relative performance evaluation shields CEO pay from the effects of luck and, *ceteris paribus*, will result in higher CEO pay when an industry underperforms than a compensation structure that penalizes bad luck. However, this higher pay is not a form of rent extraction, but is, instead, simply a consequence of efficient contracting when sector performance is negative. In contrast, when sector performance is positive, a compensation structure that rewards good luck will result in higher CEO pay than a compensation structure that shields CEO pay from the effects of good luck through relative performance evaluation. In summary, the pay-premium that can occur when CEOs are rewarded for good luck suggests *inefficient* pay practices and rent extraction. However, no pay-premium is expected when CEOs are "rewarded" for bad luck. Instead, the pay-premium, if any, is expected when CEO pay is shielded from the effect of bad luck and thus suggestive of *efficient* pay practices but not rent extraction. Thus, I do not use the sensitivity of CEO pay to negative sector returns to classify CEOs by potential rent extraction.

I acknowledge that my measure of pay-for-luck sensitivity has limitations as an index of contracting efficiency and rent extraction. First, industry-size returns may be a poor measure of exogenous factors compared to benchmarks that are tailor-made for a firm. Second, there may be instances where the principal would find it beneficial to tie CEO compensation to exogenous factors (Lambert 2001; Oyer 2004). Third, as a practical matter, it is unlikely that the principal can ever completely remove the effect of exogenous factors from performance measures. Thus, a second-best compensation contract will expose the agent to some good and bad luck as a necessary consequence of relying on contractible performance measures.

The third hypothesis predicts that the rate of growth in CEO compensation in the pre-expensing period is higher when CEO pay is more sensitive to good luck. Additionally, if SFAS 123(R) makes compensation rents more visible, then the third hypothesis predicts that the reduction in the rate of growth in CEO compensation following the adoption of SFAS 123(R) is greater for those CEOs whose pay is more sensitive to good luck under SFAS 123.[2]

> **H3:** Firms with CEOs whose compensation is highly sensitive to good luck in the pre-expensing period will have higher rates of growth in CEO compensation in that period and greater reductions in the rates of growth in compensation after the adoption of SFAS 123(R) compared to firms with CEOs whose compensation is less sensitive to good luck under SFAS 123.

---

[2] There is a plausible alternative prediction. Favorable CEO pay for luck under SFAS 123 might, in part, result from entrenched managers who, as argued in H2, are likely to limit the consequences of the increased transparency that results from SFAS 123(R). If pay for luck in the pre-expensing period is considered a proxy for managerial power that results in rent extraction, then H3 becomes a test of the relative influence of managerial power and reporting transparency. H3 is stated under the assumption that reporting transparency will have the dominant influence.

IV. RESEARCH DESIGN

Preliminary Tests

H1 through H3 assume that SFAS 123(R) affects pay levels and pay mix. The following model is therefore estimated as a preliminary step for each component of CEO compensation:

$$\ln C_{it} = \alpha_0 + \alpha_1 TREND_{ij} + \alpha_2 FAS_{it} + \beta_1 R_{it} + \beta_2 DIV_{it} + \beta_3 CFLOW_{it} + \beta_4 BM_{it-1} + \beta_5 \ln SALES_{it-1} + \beta_6 IR_{it-1} + \beta_7 \ln C_{it-1} + \varepsilon_{it}, \quad (1)$$

where $t = 0$ is the first year a firm used option expensing; $\ln C_{it}$ is the log of CEO compensation, with C representing any one of five CEO pay components (option grants, stock grants, equity grants, cash compensation, and total compensation); *TREND* is a variable that indexes by fiscal year j (calendar time) and thus controls for regulatory and other systematic factors that may have affected compensation; FAS_{it} is an indicator variable that equals 1 when $t \geq 0$, and 0 otherwise; R_{it} is the stock return for firm i in year t; *DIV* is a dividend constraint indicator; *CFLOW* is cash flow shortfall; *BM* is book-to-market; ln*SALES* is the log of sales; and *IR* is the incentive residual from the Core and Guay (1999) model. Appendix A provides formal definitions for all variables.

The control variables *DIV*, *CFLOW*, *BM*, ln*SALES*, and *IR* follow Core and Guay (1999). I use the same model for all pay components (including cash pay) to facilitate comparison. For equity grants, the coefficient on *BM* should be negative because lower growth firms are expected to make smaller equity grants; the coefficients on *CFLOW* and *DIV* should be positive because firms are expected to have a preference for equity compensation when they are cash or dividend constrained; and the coefficient on *IR* should be negative because equity grants in year t are expected to be higher (lower) when a CEO's equity incentives in year $t-1$ are below (above) their expected value (Core and Guay 1999). For all forms of compensation, the coefficient on ln*SALES* should be positive to reflect higher CEO pay in larger firms.

I expect the coefficient on firm performance (R) to be positive, consistent with pay for performance. The model includes lagged compensation ($\ln C_{it-1}$) to allow for "stickiness" in pay practices (Carter et al. 2007). With $\ln C_{it-1}$ in the model, the coefficient on FAS reflects the difference between the rate of change in compensation in the post-expensing period and the rate of change in the pre-expensing period, after controlling for the effect of other factors.[3]

Tests of Hypotheses 1 and 2

The first hypothesis (H1) predicts that, after the adoption of option expensing, the reduction in the growth in option pay, increase in the growth in stock grants, and reduction in the growth in total pay will be more pronounced for firms with greater reporting benefits from option grants in the pre-expensing period. The regression model is:

$$\ln C_{it} = \alpha_0 + \alpha_1 TREND_{ij} + \alpha_2 FAS_{it} + \alpha_3 OPTEXP_i + \alpha_4 (OPTEXP_i * FAS_{it}) + \beta_1 R_{it} + CONTROLS + \varepsilon_{it}, \quad (2)$$

where *OPTEXP* is an index that ranks firms by reporting benefits of option grants to all employees as a group during the pre-expensing period, *CONTROLS* refers to firm-specific control variables from Equation (1), and other variables are as previously defined.

---

[3] For example, consider a case where compensation decreases by 5 percent per year in the pre-expensing period and 20 percent in the post-expensing period. Assuming that compensation is completely determined by the decay rates (5 percent and 20 percent) and using the model $\ln C_{it} = \alpha + \beta_1 \ln C_{it-1} + \beta_2 FAS_{it} + \varepsilon_i$, the coefficient $\alpha = -0.05129$, $\beta_1 = 1$, and $\beta_2 = -0.17185$. The decay rate in the pre-implementation period is equal to $\exp(-0.05129) - 1 = -0.05$; and, the change in decay rate is found as $\exp(-0.05129 - 0.17185) - \exp(-0.05129) = -0.15$.

For *OPTEXP*, I first find each firm's median IOE_{it} from $t \leq -2$, where IOE_{it} is equal to the implied option expense in year t for firm i scaled by market value of equity (Aboody et al. 2004). Next, I rank median IOEs from 0 to 1 to form *OPTEXP*.[4] Higher values of *OPTEXP* represent more favorable income effects (reporting benefits) from option grants *vis-à-vis* alternative forms of compensation in the pre-expensing period. As discussed above, H1 is conditioned on $\alpha_2 < 0$ for option grants and total pay, and $\alpha_2 > 0$ for restricted stock grants. H1 predicts that the effect of requiring options to be expensed will be increasing in the extent to which the firm relied on options for employee compensation prior to the expensing requirement, such that $\alpha_4 < 0$ for CEO option grants and total pay, and $\alpha_4 > 0$ for CEO stock grants.

The second hypothesis (H2) predicts that more entrenched CEOs will experience higher growth in option and total pay in the pre-expensing period and will experience a less severe post-expensing reduction in option and total pay than less entrenched CEOs. The model is:

$$\ln C_{it} = \alpha_0 + \alpha_1 TREND_{ij} + \alpha_2 FAS_{it} + \alpha_3 EINDEX_i + \alpha_4 (EINDEX_i * FAS_{it}) + \beta_1 R_{it} + CONTROLS + \varepsilon_{it}, \tag{3}$$

where $EINDEX_i$ is the median of firm i's entrenchment index (Bebchuk et al. 2009) from its pre-expensing period ($t \leq -2$), and other variables are as defined previously. *EINDEX* ranges from 0 to 6, with higher values indicating more deeply entrenched management. H2 predicts $\alpha_3 > 0$ and $\alpha_4 > 0$ for option grants and total pay.

Tests of Hypothesis 3

For the third hypothesis (H3), I use an index of pay for good luck as a measure of rent extraction. Using an adaptation of the procedure in Bertrand and Mullainathan (2001), I separately estimate for each firm the sensitivity of CEO pay to good and bad luck. Let R_{ij} equal the return for firm i in fiscal year j and R_j equal the average return for the matching industry-size portfolio. The industry-size benchmark return, R_j, represents that portion of firm stock return in year j due to sector performance or observable luck. $R_{ij} - R_j$ represents firm performance due to managerial skill and unobservable luck.

Next, I define three new variables: luck ($L = R_j$), good luck (*GL*), and bad luck (*BL*), where $GL = \max(0,L)$ and $BL = \min(0,L)$. I then estimate the following time-series equation for each firm:

$$\ln C_{ij} = \alpha_i + \beta_i R_{ij} + \gamma_i GL_{ij} + \tau_i BL_{ij} + \varepsilon_{ij}, \tag{4}$$

where $\ln C_{ij}$ is the natural log of compensation for firm i in fiscal year j. Under relative performance evaluation, the coefficients γ_i and τ_i should equal $-1 * \beta_i$, which can be seen by expanding Equation (4), with $R_{ij} = S_{ij} + GL_{ij} + BL_{ij}$, where S_{ij} is the performance due to skill (and unobservable luck). In other words, the effect of observable luck should be completely removed from performance measures, consistent with relative performance evaluation. In the presence of pay for good luck, by contrast, γ_i will exceed $-1 * \beta_i$. When $\gamma_i = 0$, good luck is rewarded as much as skill. Notice that pay for good luck (γ_i) is measured relative to each firm's pay for skill (β_i).

I use Equation (4) to find good luck pay sensitivity, γ_i, for each pay component separately, based on time-series data for the period prior to adoption of option expensing. I exclude a CEO's compensation in the CEO's first year in the position because pay that year is atypical (Rajgopal et al. 2012) and usually for less than a full year. Because option, stock, and equity compensation are censored at zero, I use a Tobit formulation for these pay components. Cash and total compensation regressions are based on OLS.

---

[4] As an illustration, Magnetek, Inc. has nine years of pre-expensing data for this calculation, starting in fiscal 1996 ($t = -10$) and ending with fiscal 2004 ($t = -2$). For each year, I calculate IOE_{it} (Compustat's implied option expense [$XINTOPT_{it}$] scaled by market value of equity [$CSHO_{it} \times PRCC\_F_{it}$]). For Magnetek, IOE ranges from a low of 0.0019 to a high of 0.0398, with a median value over the nine years of 0.0103. I repeat this process for each of the 1,048 firms in the restricted sample from Table 1. For Magnetek, *OPTEXP* is 0.8885. This means that, in my sample, Magnetek's median pre-expensing IOE stands at the 89th percentile.

H3 predicts that higher pay for good luck (γ_i) under SFAS 123 will be associated with higher growth in CEO compensation in the pre-expensing period and a larger reduction in the growth in CEO compensation after SFAS 123(R). The model is:

$$\ln C_{it} = \alpha_0 + \alpha_1 TREND_{ij} + \alpha_2 FAS_{it} + \alpha_3 PGL_i + \alpha_4 (PGL_i * FAS_{it}) + \beta_1 R_{it} + CONTROLS + \varepsilon_{it}, \tag{5}$$

where PGL_i is an indicator variable equal to 1 when γ_i is greater than the sample median, and 0 otherwise. Hence, *PGL* is 1 when CEO pay is abnormally sensitive to good luck relative to its sensitivity to CEO skill, consistent with a compensation policy that is comparatively CEO-friendly. H3 predicts that $\alpha_3 > 0$, consistent with CEO compensation rents in the pre-expensing period when pay is unusually sensitive to good luck under SFAS 123. H3 further predicts that $\alpha_4 < 0$, consistent with a larger reduction in the growth in CEO compensation after SFAS 123(R) for CEO's with compensation rents under SFAS 123.[5]

V. SAMPLE SELECTION AND DESCRIPTIVE STATISTICS

Sample Selection

Table 1 reports the frequency of the intrinsic value method of accounting for option grants (i.e., no expensing) versus the grant-date fair value method (i.e., expensing) over calendar time from 1998 to 2007 and over event time from $t = -4$ to $t = +4$, where $t = 0$ is the first year a company expensed option grants. Any firm adopting the grant-date fair value method prior to fiscal 2006 did so voluntarily. For voluntary adopters, I define the adoption date as the earlier of the adoption date reported by McConnell et al. (2004) or the Compustat adoption date. (See Appendix A for additional discussion.)

Table 1 reports frequency data for two sets of firms. In the first six columns of Table 1, frequency counts are restricted to firm-years with asset (Compustat), compensation (ExecuComp), and market return data (CRSP), and at least five other firms in their industry-size portfolio with market return data. The last six columns further restrict the sample to firms with data required for regression Equation (1) for the five years from $t = -3$ to $t = +1$. Comparing the two samples illustrates the reduction in sample size due to primary data requirements. For example, at $t = 0$, there are 1,527 firms in the initial sample and 1,048 in the sample of firms with five years of continuous data.

---

[5] In robustness tests, I include in my regression models the variable *PBL* (pay for bad luck), which is equal to 1 when the sensitivity of CEO pay to bad luck, τ_i, is *less than* the sample median, and 0 otherwise. As with good luck sensitivity, the sensitivity of CEO pay to bad luck, τ_i, is negative when a firm uses relative performance evaluation to at least partially remove the contribution that bad luck made to firm performance, and greater than or equal to 0 when a firm "rewards" bad luck as much as or more than a CEO's contribution to firm performance. Thus, *PBL* is 1 when a CEO's pay is shielded from the effects of bad luck more than average and thus not only comparatively CEO-friendly, but also *consistent* with relative performance evaluation. As discussed earlier, τ_i is not a useful way to capture differences between firms with respect to compensation rents because, *ceteris paribus*, CEO pay will be higher when pay is shielded from the effect of bad luck even though that pay practice is *consistent* with relative performance evaluation. By contrast, a CEO-friendly compensation policy with respect to good luck (where γ_i is *greater than* the sample median and $PGL = 1$) is *inconsistent* with agency theory. When I include *PBL* in the regression model, inferences are unchanged; *PBL* is significant only for cash compensation.

TABLE 1

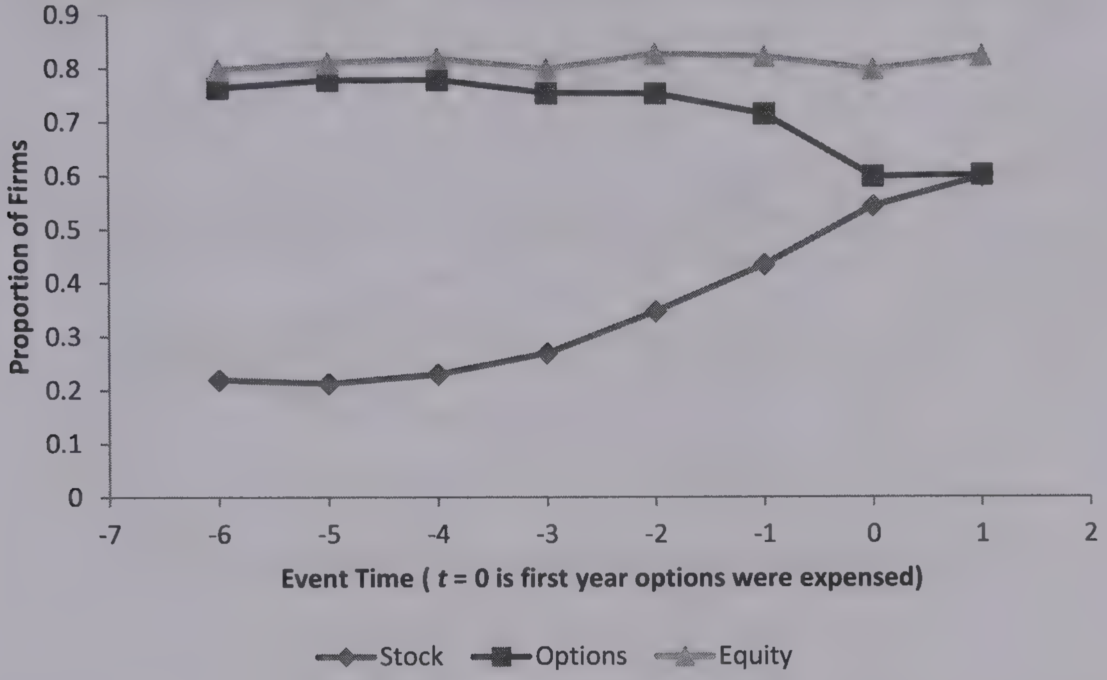
Sample Distribution

The Frequency of the Intrinsic Value Method (No Expensing) and the Grant-Date Fair Value Method (Expensing) of Accounting for Option Grants by ExecuComp Firms Classified by Fiscal Year and Event Time

Firms with Return, Assets, and Compensation Data						Firms with Data for Equation (1) over $t = <-3,+1>$					
Fiscal Year (j)	Intrinsic Value Method	Grant-Date FV Method	Event Time (t)	Intrinsic Value Method	Grant-Date FV Method	Fiscal Year (j)	Intrinsic Value Method	Grant-Date FV Method	Event Time (t)	Intrinsic Value Method	Grant-Date FV Method
1998	1038	3	−4	1288		1998	951	1	−4	1047	
1999	1152	3	−3	1358		1999	987	1	−3	1048	
2000	1268	4	−2	1411		2000	1012	1	−2	1048	
2001	1278	5	−1	1502		2001	1033	1	−1	1048	
2002	1291	30	0		1527	2002	1034	12	0		1048
2003	1193	196	1		1459	2003	926	122	1		1048
2004	1216	223	2		483	2004	910	138	2		329
2005	1233	287	3		227	2005	860	182	3		130
2006		1529	4		190	2006		1034	4		106
2007		1447				2007		1028			

Table 1 is restricted to ExecuComp firms with Compustat and CRSP coverage. The "Intrinsic Value Method" column reports the number of firms using the intrinsic value method of accounting for option grants (no expense) and the "Grant-Date FV Method" column reports the number of firms using grant-date fair value method of accounting for option grants (expensing).The first six columns are limited to any firm with data for market return, assets, compensation, and at least five other firms in their industry-size peer group in the indicated year. A firm's peer group is defined as all firms in the same industry (four-digit GIC code) and in the same market size quartile within the industry. The last six columns are further limited to firms with all data needed for Equation (1) over the five years $t = -3$ to $t = +1$. For each sample, the first three columns report the number of firms with data available in each fiscal year, classifying firms by whether they used the intrinsic value method or the grant-date fair value method in fiscal year j, and the next three columns report the number of firms with data available in each year over event time t, where $t = 0$ is the first year a firm expensed option grants.

FIGURE 1
Proportion of Firms Making Stock, Option, or Equity Grants to Their CEOs



Descriptive Statistics

Figure 1 plots the proportion of firms making option, stock, and equity grants to their CEOs over $t = -6$ to $t = +1$. In Figure 1, the proportion of firms granting options declines and the proportion granting restricted stock increases beginning from year $t = -5$ to year $t = -4$. The proportion of firms granting one or both forms of equity is almost flat at about 80 percent.

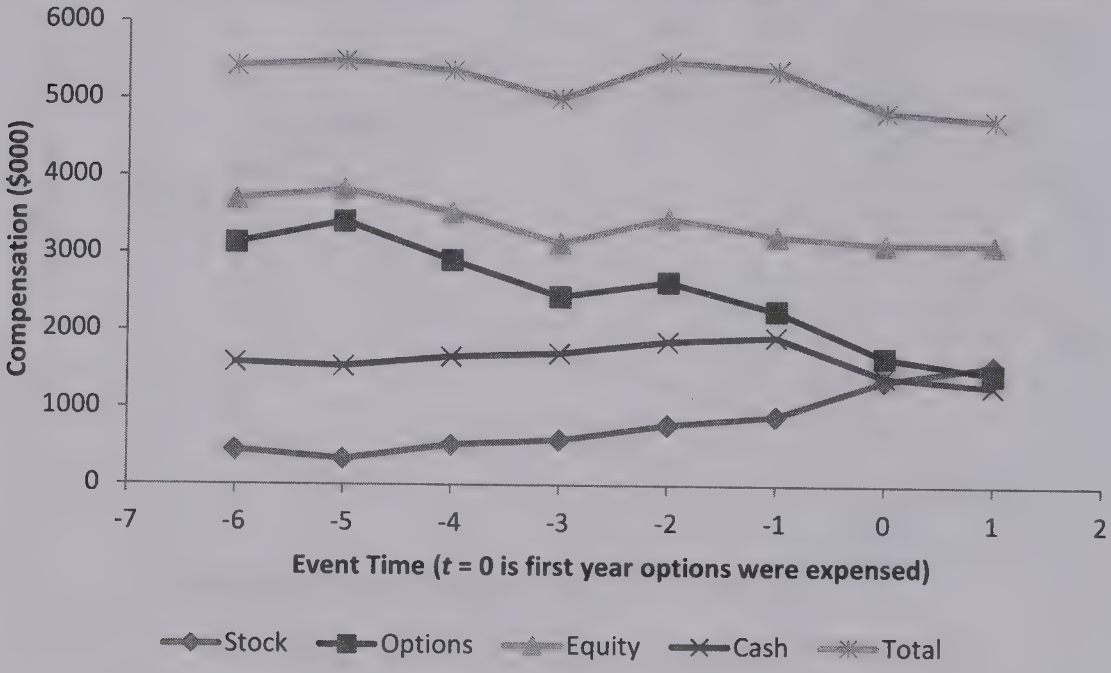
Figure 2 plots mean CEO compensation in thousands of dollars for each of five CEO pay components (stock grants, option grants, equity grants, cash compensation, and total compensation) over the same period, with each component adjusted to constant 2007 dollars based on the Consumer Price Index. Figure 2 shows similarly that mean option grants decline and mean restricted stock grants increase from year $t = -5$ to year $t = -4$. The average total equity grant is relatively constant over time, particularly after $t = -3$. The peak year for option grants in dollars and in proportion of total compensation is $t = -5$. For most of the sample, $t = -5$ is calendar year 2000, which is five years before SFAS 123(R) became mandatory, shortly after the top of the technology stock bubble, and shortly before several major accounting scandals. Both graphs are based on the initial sample of firms from Table 1. The graphs are very similar for the smaller sample.

Panel A of Table 2 provides descriptive statistics for the restricted sample from Table 1. The left side of Panel A reports separate columns for the pre- ($t = < -3,-2 >$) and post- ($t = < 0,+1 >$) expensing periods. These sample statistics are based on 4,192 firm-years (n = 1,048 firms × 4 years), split evenly between pre-expensing (n = 1,048 firms × 2 years) and post-expensing periods. I find no systematic differences between the initial sample (not tabulated) and the restricted sample.

From the pre-expensing to the post-expensing period, the average annual CEO option grant decreases significantly (p-values not tabulated) from $2.555m to $1.566m, the average restricted stock grant increases significantly from $0.686m to $1.499m, and the average equity compensation decreases, but insignificantly, from $3.308m to $3.153m. Mean cash and total compensation both decrease significantly after firms start to expense option grants, consistent with a reduction in CEO

FIGURE 2

Mean Value of CEO Stock, Option, Equity, Cash, and Total Compensation



compensation rents. The proportion of firms granting options decreases significantly from 75.7 percent to 60.4 percent, the proportion granting restricted stock increases significantly from 30.7 percent to 58.5 percent, and the proportion granting equity increases, but insignificantly, from 81.5 percent to 82.4 percent (not tabulated).[6]

The right side of Panel A provides descriptive statistics for management entrenchment, implied option expense, and pay for luck with one value per firm. The sample sizes are less than 1,048 due to data requirements. Management entrenchment (*EINDEX*) and implied option expense (*IOEmedian*) are median values from firms' pre-expensing periods. Measures of pay for good luck (*GAMMA*) and pay for bad luck (*TAU*) are log transformations of γ and τ, respectively. (See Appendix A.)

Implied option expense (*IOEmedian*) averages 0.56 percent of market capitalization, and ranges from 0 percent to 21.38 percent. The *mean* values for *TAU* and *GAMMA* are negative for option grants, equity grants, and cash compensation, indicating that these CEO pay components are at least partially adjusted for sector performance and, thus, weakly consistent with relative performance evaluation. On the other hand, *median* values for *TAU* and *GAMMA* indicate pay-for-luck asymmetry that is advantageous to CEOs. The median values for *TAU* are negative for all pay components (except stock grants), and the median values for *GAMMA* are positive for all pay components (except option grants). Thus, most of the firms in the sample at least partially shielded CEO compensation from the effects of unfavorable peer-group performance (bad luck), but most did not shield CEO compensation from the effects of favorable peer-group performance (good

---

[6] In tests for changes in means, I use the non-parametric Wilcoxon rank-sums test for option and stock compensation to allow for the non-normality of their truncated distributions, and the parametric t-test for the other pay components. p-values (two-tailed) are < 0.001 for options, stock, and cash compensation, 0.070 for total compensation, and 0.552 for equity compensation. Changes in proportion are based on the Chi-square test. p-values are < 0.001 for option and stock compensation, and 0.470 for equity compensation.

TABLE 2

Descriptive Statistics

Panel A: Descriptive Statistics for Variables Used in Tests of H1 through H3, for the Restricted Sample in Table 1

Variables with Annual Values[a]

Variable[c]	n	Means $t = -3,-2$	Means $t = 0,+1$	Min.	Max.
O_{it} (\$000)	4192	2,555	1,566	0	27,028
S_{it} (\$000)	4192	686	1,499	0	11,471
EC_{it} (\$000)	4192	3,308	3,153	0	31,996
TCC_{it} (\$000)	4192	1,795	1,341	55	8,571
TC_{it} (\$000)	4192	5,261	4,805	188	37,885
R_{it}	4192	0.296	0.115	−0.731	2.670
L_{it}	4192	0.336	0.147	−0.438	1.425
GL_{it}	4192	0.353	0.165	0.000	1.425
BL_{it}	4192	−0.016	−0.018	−0.438	0.000

Cash pay	989	−0.158	−0.258	−3.312	3.847
Total pay	992	−0.276	−0.594	−3.549	4.077

---

[a] For annual variables, means are reported separately for the pre-expensing period when the intrinsic value method of option grant accounting was employed ($t = -3,-2$) and the post-expensing period when the grant-date fair value method was employed ($t = 0,+1$). The year prior to grant-date fair value adoption ($t = -1$) is omitted from the tabulation.

[b] Variables found once per firm are from the pre-expensing period as described in the paper.

[c] See Appendix A for variable definitions. O_{it}, S_{it}, and EC_{it} are for all firms regardless of whether they made equity grants. CEO compensation (O, S, EC, TCC, and TC) is in constant dollars with 2007 as the base year. GL_{it} and BL_{it} are for firms with non-zero values for GL_{it} and BL_{it}, respectively. Variables are winsorized at the 1st and 99th percentile, except those that are log transformed.

[d] The small number of pay-for-luck estimates for stock grants is due to the low frequency of stock compensation during the pre-expensing period for sample firms.

luck). Instead, for most of the firms in the sample, the sensitivity of CEO pay to favorable peer-group performance is greater than the sensitivity of CEO pay to firm-specific performance (i.e., a firm's stock return less the mean return for the firm's industry-size peer group). The results suggest that a majority of firms use relative performance evaluation for bad luck but not good luck and that, while pay-for-luck practices vary considerably across firms, most firms reward good luck at least as much as firm-specific performance.

Panel B of Table 2 provides Pearson correlation statistics for key sample variables. As expected, CEO compensation (in log form) and $\ln SALES_{t-1}$ are positively correlated, ranging from 0.22 for option compensation ($\ln O$) to 0.56 for total compensation ($\ln TC$). The positive correlation (0.25) between equity and cash pay ($\ln EC$ and $\ln TCC$) is consistent with common factors, including size, affecting both forms of compensation. As would be expected, firm stock return (R) is positively correlated with good luck (GL;+0.50) and bad luck (BL;+0.27).

VI. REGRESSION RESULTS

Preliminary Analysis

Table 3 reports the results for Equation (1), which tests for changes in growth in CEO pay components following the adoption of option expensing. I use a Tobit model for option, restricted stock, and equity grants to allow for censoring of the dependent variable at 0,[7] and an OLS regression model for cash and total compensation. The analyses in Table 3 (and Tables 4 through 7) include the two years before ($t = -3$, $t = -2$) and the two years after ($t = 0$, $t = +1$) the adoption of option expensing for the 1,048 firms with continuous data over $t = -3$ to $t = +1$ (see Table 1). The "transition" year preceding adoption ($t = -1$) is excluded because CEO compensation in that year may have been influenced by anticipated option expensing and, therefore, may not be representative of either pre- or post-expensing CEO pay.[8]

The coefficients on *FAS* indicate that, compared to their growth rates in the pre-expensing period, option grants *decrease* and restricted stock grants *increase* when firms adopt option expensing (p-values < 0.001, p-values two-tailed).[9] These findings are consistent with both the perceived cost hypothesis and prior research for voluntary option expensing (Carter et al. 2007). The rate of growth in total equity compensation also decreases significantly ($p = 0.037$), consistent with Brown and Lee (2007) who find less than a dollar-for-dollar substitution of stock for option grants in anticipation of SFAS 123(R).

The rate of growth in cash and total compensation both decrease after firms adopt option expensing. This result is consistent with improved transparency and heightened concern over potential political costs when all forms of compensation are expensed. After controlling for other factors affecting CEO compensation, the coefficient on *FAS* in the total compensation regression indicates that, on average, the rate of change in total CEO compensation for the sample firms

---

[7] An alternative to Tobit is the Heckman procedure, which would provide estimates of both the probability of observing an equity grant and the determinants of the expected level of equity pay conditional on a grant. The Tobit procedure is constrained such that the independent variables and coefficients on those variables are the same for both the selection and the outcome equation (Breen 1996). I use the Tobit model in the interest of parsimony given the analysis of multiple pay components.

[8] Using $t = -4$ to $t = -2$ as the pre-expensing period and $t = -1$ to $t = +1$ as the post-expensing period, I find results that are qualitatively the same as those presented here.

[9] Technically, for the Tobit specifications, the correct statement is "compared to their probability and growth rates in the pre-expensing period, the probability of and rate of growth in option grants *decrease*, and the probability of and rate of growth in restricted stock grants *increase*." The simpler construction is used for brevity and consistency of expression.

Other variables have a two-tailed p-value of 0.10 or higher.

[a] Dependent variable is the log of compensation granted to CEO of firm *i* in year *t*. Parameter estimate is listed above and t-statistic below for each independent variable. See Appendix A for variable definitions. $\ln C_{it-1}$ refers to the log of lagged compensation for the type of compensation represented in a regression model.

following the implementation of SFAS 123(R) is approximately 11.2 percentage points lower than the rate of change in the pre-expensing period ($-0.112 = \exp(-0.119) - 1$).

Results for control variables are consistent with expectations. All pay components are positively associated with their lagged values ($\ln C_{it-1}$) and with firm size ($\ln SALES_{t-1}$) (p-values < 0.001). The association between firm performance (R) and compensation is positive and significant for cash, equity, and total pay (p-values $\leq$ 0.036), weakly positive for option pay (p-value = 0.089), and insignificant for stock grants. As expected, equity and total compensation are negatively associated with BM_{it-1} and IR_{it-1} (p-values $\leq$ 0.01) and positively associated with dividend constraints (DIV) (p-values $\leq$ 0.040). Only option compensation is significantly and positively associated with cash flow constraints ($CFLOW$) (p-values = 0.018). Because cash compensation is largely independent of BM, IR, and DIV, the association between total compensation and those three variables is apparently due to equity compensation effects that flow through to total compensation. In summary, after controlling for other factors known to affect CEO compensation, the results in Table 3 show that option expensing is associated with a change in the mix of compensation components and a decrease in the rates of growth in cash and total compensation for sample firms over the two years after versus before SFAS 123(R) adoption.

Results for H1

If financial reporting considerations were unimportant to compensation design choices under SFAS 123, then there would be no association between the effect that employee stock option grants had on pre-expensing reported income and subsequent changes in the rate of growth in CEO compensation. The perceived cost hypothesis maintains that financial reporting considerations did play a key role in compensation decisions. Building on the perceived cost hypothesis, H1 predicts that the effect of SFAS 123(R) on CEO compensation will be increasing in the extent to which firms relied on employee option compensation under SFAS 123.

The regression model for H1 in Table 4 differs from the model in Table 3 by the inclusion of *OPTEXP* (the 0 to 1 ranking of firms by median implied option compensation expense under SFAS 123) and $OPTEXP * FAS$. In Table 4, the coefficient on *OPTEXP* is positive for option grants ($p\text{-value} = 0.002$) and negative for stock grants ($p\text{-value} = 0.011$). In other words, the rate of growth in CEO option compensation is increasing and the rate of growth in CEO stock compensation is decreasing in the pre-expensing period as implied option expense increases. Consistent with H1, the coefficient on the interaction term $OPTEXP * FAS$ is negative and significant for option grants ($p\text{-value} = 0.024$) and positive and significant for restricted stock grants ($p\text{-value} = 0.014$). Thus, both the decline in the growth rate in option grants and the increase in the growth rate in restricted stock grants in the post-expensing period are larger, on average, for firms with higher levels of implied option expense in the pre-expensing period. These findings suggest that income considerations may have influenced the mix of CEO option and stock compensation under SFAS 123.

Next, consider the association between *OPTEXP* and equity and total compensation. The coefficient on *OPTEXP* is significantly positive ($p\text{-values} < 0.001$) for both compensation components. The coefficient on $OPTEXP * FAS$, however, is significantly negative for equity compensation and negative but not significant for total compensation. The results for *OPTEXP* and $OPTEXP * FAS$ for equity compensation, taken together, suggest that the reporting advantage of option compensation under SFAS 123 may have spurred a growth in equity compensation that was partially reversed when the reporting advantage of option grants ended with SFAS 123(R). On the other hand, the combined results for those two variables for total CEO compensation cast some doubt on the findings for equity compensation because I would expect the equity compensation effects to flow through to total compensation. Finally, as in Table 3, the results show that the rate of growth in CEO cash compensation decreases in the post-expensing period as shown by the negative and significant coefficient on *FAS*. However, the decrease in the rate of growth in cash pay is not associated with pre-expensing implied option compensation expense.

The results in Table 4 suggest that the reporting benefits of option compensation under SFAS 123 may have influenced some firms' compensation design choices, particularly the mix of option and stock compensation. The findings suggest that, under SFAS 123, the rate of growth in CEO option grants was higher and the rate of growth in stock grants was lower than either would otherwise have been without the financial reporting advantage of stock option compensation. The results further suggest that when reporting considerations were sufficiently important, some firms may have altered the incentive properties of CEO compensation packages in exchange for the reporting benefits of option grants.

[a] Dependent variable is the log of compensation granted to CEO of firm *i* in year *t*. Parameter estimate is listed above and t-statistic below for each independent variable. See Appendix A for variable definitions. Table 4 uses the same control variables as Table 3; results for controls are not tabulated in the interest of brevity. The coefficients and significance levels of control variables are qualitatively and quantitatively similar to those reported in Table 3.

Results for H2

This paper hypothesizes that some firms may have disguised CEO compensation rents under SFAS 123. If that is the case and if compensation rents are more transparent under SFAS 123(R), then shareholders with sufficient power to act fully in their best interests could and would enforce the elimination of rents after SFAS 123(R). Conversely, more entrenched CEOs who are protected by governance provisions that limit shareholder power would be able to preserve all or some of those rents.

In Table 5, *EINDEX* represents each firm's median entrenchment index under SFAS 123. Under H2, the coefficient on *EINDEX* is expected to be positive because I expect more entrenched CEOs to have higher rates of growth in compensation in the pre-expensing period. The results in Table 5 provide only weak support for this prediction. Of the five pay components, stock grants (p-value = 0.008) and equity compensation (p-value = 0.069) are significantly and positively associated with *EINDEX*. All other pay components are statistically independent of *EINDEX* (p-values ≥ 0.205).

The second variable of interest in Table 5 is the interaction term *EINDEX* ∗ *FAS*. Because more entrenched CEOs are expected to avoid some of the post-expensing reduction in the rate of growth in compensation, the coefficient on the interaction term is expected to be positive. Consistent with

*, **, *** Significant at the 0.10, 0.05, and 0.01 levels, respectively, using a two-tailed test.
Other variables have a two-tailed p-value of 0.10 or higher.

[a] Dependent variable is the log of compensation granted to CEO of firm *i* in year *t*. Parameter estimate is listed above and t-statistic below for each independent variable. See Appendix A for variable definitions. Table 5 uses the same control variables as Table 3; results for controls are not tabulated in the interest of brevity. The coefficients and significance levels of control variables are qualitatively and quantitatively similar to those reported in Table 3.

H2, the coefficient on $EINDEX * FAS$ is positive and significant (p-values ≤ 0.038) for options, equity, and total compensation. The post-expensing reductions in rates of growth for those three pay components are significantly less pronounced for more entrenched CEOs as predicted by H2. The change in the rate of growth in cash compensation, however, is statistically independent of management entrenchment (p-value = 0.595).

Taken as a whole, the results in Table 5 indicate that more entrenched CEOs were relatively less affected by the requirement to expense options compared to less entrenched CEOs. First, more entrenched CEOs receive higher rates of growth in restricted stock grants in the pre-expensing period (the coefficient on $EINDEX > 0$ for restricted stock). Second, they receive the same post-expensing increase in the rate of growth in restricted stock compensation as their less entrenched counterparts (the coefficient on $EINDEX * FAS$ is insignificant for restricted stock). Third, they retain more of their pre-expensing rate of growth in option compensation than their less entrenched counterparts (the coefficient on $EINDEX * FAS > 0$ for option grants).

In summary, the results suggest that more entrenched CEOs avoided some of the decrease in the rate of growth in option compensation experienced by their less entrenched counterparts and, at the same time, were able to match the increase in the rate of growth in stock grants of their less entrenched counterparts. The net effect is that more entrenched managers experienced smaller reductions in the rate of growth in equity and total compensation after SFAS 123(R) compared to less entrenched CEOs. Stated alternatively, when governance provisions gave shareholders more power to control the design of CEO compensation, firms made larger cuts in the rate of growth in CEO compensation after SFAS 123(R). The results suggest that SFAS 123 may have helped conceal inefficient, CEO-preferential pay practices and that SFAS 123(R) may have contributed to the reduction in those CEO compensation inefficiencies through more transparent reporting of the total economic cost of employee compensation.

Results for H3

Rewarding CEOs for positive sector performance (i.e., positive industry-size stock returns), which I term rewarding good luck, is a form of rent extraction that generally results in higher compensation, *ceteris paribus*. Thus, H3 predicts that compensation in the pre-expensing period will be higher for CEOs whose compensation is unusually sensitive to positive sector performance under SFAS 123. H3 further predicts that SFAS 123(R) will reduce compensation rents, leading to the expectation that the post-expensing reduction in CEO compensation will be greater when CEO pay is unusually sensitive to good sector performance under SFAS 123.

In Table 6, *PGL* is an indicator variable equal to 1 when the sensitivity of pay to good luck (γ) is above the sample median, and 0 otherwise. Pay-for-luck sensitivities are firm-specific and *ex ante* to any post-expensing compensation changes. *PGL* is derived separately for cash and total compensation. For option and stock compensation, however, I base *PGL* on pay-for-luck sensitivities for total *equity* compensation for two reasons. First, basing *PGL* on option and stock grants on total equity compensation, rather than separately on option and stock grants, increases the number of usable observations dramatically as seen in Table 2, Panel A. Second, stock and option compensation are, to some degree, substitutes, suggesting that pay-for-luck sensitivities for option and stock grants will be observed most reliably through total equity grants.

The earlier results in Panel A of Table 2 indicate that, for the majority of firms, CEO cash compensation, equity compensation, and total compensation in the pre-expensing period are more sensitive to good sector performance or good luck than to firm performance adjusted for sector performance or CEO skill. Thus, *PGL* is 1 for firms that compensated CEOs for good luck in a way that was unusually advantageous to their CEOs and inconsistent with relative performance evaluation.

The results in Table 6 are consistent with H3. The coefficient on *PGL* is positive and significant for all components of CEO compensation (p-values ≤ 0.012), indicating that the rate of growth in CEO pay in the pre-expensing period is higher, on average, when CEO pay is unusually sensitive to good luck in the pre-expensing period. The coefficient on the interaction term $PGL * FAS$ is negative and significant for option, equity, cash, and total compensation (p-values ≤ 0.042) and negative and marginally significant for restricted stock compensation (p-value $= 0.076$). On average, there is a greater reduction in the rate of growth in option, equity, cash, and total compensation and a smaller increase in the rate of growth in restricted stock grants after the implementation of SFAS 123(R) when CEO pay is unusually sensitive to good luck in the pre-expensing period.

The results in Table 6 provide new evidence about the potential negative consequences of pay for luck. When firms deviated more than normally from relative performance evaluation by compensating CEOs for good sector performance, CEOs received unusually high rates of growth in annual compensation under SFAS 123. The results suggest that rewarding CEOs for good luck was a potential source of CEO compensation rents. Additionally, the post-expensing reduction in the rate of growth in CEO compensation was largest for CEOs whose annual compensation was most sensitive to good sector performance in the pre-expensing period. The evidence suggests that, for

some firms, rent extraction occurred under SFAS 123 and that there was reduction in those compensation rents after the implementation of SFAS 123(R).

Simultaneous Test of *OPTEXP*, *EINDEX*, and *PGL*

Table 7 reports the results of compensation regressions that simultaneously include implied employee option expense, management entrenchment, and the sensitivity of CEO pay to good luck. Two considerations warrant the additional analysis. First, the results for implied option expense in Table 4 and pay for good luck in Table 6 are similar, making it possible that the two measures capture a single phenomenon. This concern is compounded by the fact that, *ceteris paribus*, options awarded for good luck will lead to higher option grants. Thus, options awarded for good luck may partially explain cross-sectional differences in aggregate-employee implied option expense, particularly if pay for good luck extended to all or most employees. Second, entrenched managers may be more successful at arguing for pay for good luck, leading to an expectation that powerful managers are an underlying characteristic of firms that pay for good luck. Table 7 protects against a potential correlated omitted variables problem that might otherwise bias coefficient estimates.

The results in Table 7 show that the findings in Tables 4 through 6 are robust to the simultaneous inclusion of entrenchment, pay for good luck, and implied option expense in the

*, **, *** Significant at the 0.10, 0.05, and 0.01 levels, respectively, using a two-tailed test.
Other variables have a two-tailed p-value of 0.10 or higher.

[a] Dependent variable is the log of compensation granted to CEO of firm *i* in year *t*. Parameter estimate is listed above and t-statistic below for each independent variable. See Appendix A for variable definitions. Table 7 uses the same control variables as Table 3; results for controls are not tabulated in the interest of brevity. The coefficients and significance levels of control variables are qualitatively and quantitatively similar to those reported in Table 3.

compensation regressions. The three measures appear to capture three different constructs that operate relatively independently in terms of their association with rates of growth in CEO pay components that occur before options were expensed and with changes in rates of growth in CEO pay components that occur after the adoption of option expensing. *PGL* is associated with higher rates of growth in compensation in the pre-expensing period for all pay components. The favorable income effect of option grants (*OPTEXP*) is associated with higher rates of growth in option and equity grants and lower rates of growth in stock grants under SFAS 123 and a more pronounced reversal in the rates of growth in those pay components after SFAS 123(R) adoption, consistent with reporting considerations that favored option grants over stock grants under SFAS 123. The favorable rate of growth associated with pay for good luck in the pre-expensing period is partially reversed after option expensing. The reduction in the growth in pay that occurs after SFAS 123(R) adoption is smaller for more entrenched CEOs.

VIII. SUMMARY AND CONCLUSION

This study provides evidence that the implementation of SFAS 123(R) is associated with changes in CEO compensation that are beneficial to shareholders. The evidence supports the conclusion that SFAS 123 generated favorable compensation consequences for CEOs but potentially negative economic consequences for shareholders. The first set of findings suggests that the earnings advantage of option grants under SFAS 123 influenced the mix of option and stock compensation that firms chose to offer. When firms lost the reported income advantage associated with option grants, there was a reduction in the rate of growth in CEO option compensation and an increase in the rate of growth in CEO stock compensation. Moreover, both changes in growth rates are more pronounced in firms with the larger favorable income effects from option grants under SFAS 123. These results suggest that some firms allowed reported income effects to influence the option/stock compensation mix decision under SFAS 123. The results further suggest that reported income effects may have led firms to sacrifice incentive considerations in their design of CEO compensation.

I also find that entrenched CEOs are less affected by some of the changes in CEO compensation that occurred with the implementation of SFAS 123(R). Firms with deeply entrenched managers have governance provisions that limit shareholder rights to replace, and therefore discipline, management. As management entrenchment diminishes, shareholder rights to replace and discipline the CEO increase. The findings show that the reduction in the rate of growth in CEO compensation after SFAS 123(R) is larger in firms where shareholders had relatively more power to discipline the CEO. Rational shareholders with sufficient power over the CEO would not be expected to reduce the rate of growth in CEO compensation unless compensation rents were evident. These results suggest that SFAS 123(R) is associated with a restructuring of CEO compensation in ways that were beneficial to shareholders.

In a novel set of tests, I find that when CEO pay is unusually sensitive to good sector performance or good luck under SFAS 123, the rate of growth in CEO compensation in the pre-expensing period is higher, and that the reduction in the rate of growth after SFAS 123(R) is greater. Rewarding CEOs for good sector performance is inconsistent with relative performance evaluation and a potential source of CEO compensation rents. The findings suggest that the reduction in the rate of growth in CEO compensation after SFAS 123(R) is larger in firms that paid larger CEO compensation rents under SFAS 123. Taken as a whole, this study provides evidence that changes in CEO compensation practices that occurred after SFAS 123(R) are beneficial to shareholders.

APPENDIX A

VARIABLE DEFINITIONS

Acronym	Description	Calculation[a]
BM_{it}	book-to-market	book value of assets (*AT*)/[book value of liabilities $(AT - SEQ)$ + market value of equity (*PRCC_F* × *CSHO*)];
C_{it}, $\ln C_{it}$	CEO compensation	C_{it} is compensation paid to the CEO of firm i in year t as reported by ExecuComp, where C can stand for any one of five compensation components (options, stock, equity, cash, total). Compensation is adjusted for inflation using the consumer price index with 2007 as the base year. Compensation can be one of five measures shown just below. $\ln C_{it}$ refers to $\log(1 + C_{it})$;
O, $\ln O$	option grants	grant-date fair value of option grants equal to *OPTION_AWARDS_BLK_VALUE* when available, and *OPTION_AWARDS_FV* otherwise;
S, $\ln S$	stock grants	grant-date fair value of restricted stock grants equal to *RSTKGRNT* when available, and *STOCK_AWARDS_FV* otherwise;
EC, $\ln EC$	equity compensation	total of option and restricted stock grants, found $O + S$;
TCC, $\ln TCC$	cash compensation	salary plus bonus equal to *TOTAL_CURR*;
TC, $\ln TC$	total compensation	total CEO compensation found as $EC + TCC + Other\ Pay$, where *Other Pay* is equal to *OTHERANN* when available, and *OTHCOMP* otherwise;
$CFLOW_{it}$	cash flow shortfall	prior three-year average ($t-3$ to $t-1$) of [common and preferred dividends $(DVC + DVP)$ − investing cash flow (*IVNCF*) − operating cash flow (*OANCF*)]/total assets (*AT*);
DIV_{it}	dividend constraint	indicator variable set to 1 for any firm classified as dividend constrained in any of the prior three years ($t-3$ to $t-1$), and 0 otherwise. Dividend constrained classification occurs when [retained earnings at year end (RE) + cash dividends for the year $(DVP + DVC)$ + stock repurchases during year (*PRSTKC*)]/[prior year cash dividends and stock repurchases] < 2. *DIV* is also set equal to 1 if denominator is 0 for all three years;
$E\text{-}index_{it}$	entrenchment index	entrenchment index (Bebchuk et al. 2009) for firm i in year t;
$EINDEX_i$	entrenchment index	median value of *E-index* from the pre-expensing period for firm i;
FAS_i	grant-date fair value method indicator (expensing)	indicator variable set to 1 for any year a firm used grant-date fair value accounting for option grants (expensing), and 0 for any year a firm used intrinsic value method for option grants (no expensing). The adoption year is defined as the earlier of the Bear Stearns (2004) reported grant-date fair value adoption date and the Compustat adoption date. If Compustat stock option footnote (*STKCO_FN*) equals *OE*, then a firm-year is marked an option-expensing year. The decision to supplement the Bear Stearns report with *STKCO_FN* was made after comparing Bear Stearns and Compustat data indicating the adoption year. While the Compustat adoption date indicator is unreliable for very early adopters (many false negatives), the indicator is extremely accurate for later early adopters (no false positives) based on a comparison of annual report and proxy disclosures when Compustat and Bear Stearns had different adoption years;

(continued on next page)

APPENDIX A (continued)

Acronym	Description	Calculation[a]
IOE_{it}	implied option expense	implied option expense (*XINTOPT*) in year t as a proportion of market value of equity (*CSHO* × *PRCC_F*) year-end; measured annually for each firm-year prior to option expensing. Value is expressed as a percentage in tabulations;
$IOEmedian_i$	median IOE	median values of IOE_{it} for each firm from their pre-expensing period;
$OPTEXP_i$	ranked *IOEmedian*	*IOEmed* ranked from 0 to 1. The ranking forms the observed cumulative density function for financial reporting cost in the pre-expensing period;
IR_{it}	incentive residual	residual from the Core and Guay (1999) model. *IR* represents the deviation of a CEO's equity incentives from their predicted optimal level, where equity incentives are derived from the CEO's portfolio of equity holdings (restricted stock plus options);
L_{ij}	luck	firm return (R_{ij}) attributable to peer-group performance. See R_j below;
GL_i	good luck	Max(0,*L*);
BL_i	bad luck	Min(0,*L*);
S_{ij}	skill	$R_{ij} - L_{ij}$ represents firm performance that is attributable to other than peer-group performance. See R_{ij} below;
R_{ij}	stock return	buy-and-hold stock return for fiscal year j, derived from monthly returns with dividends as reported by CRSP;
R_j	industry-size, peer group stock return	peer group mean stock return in fiscal year j for firm i, excluding firm i. A firm's peer group is defined as all firms in the same industry (four-digit GIC code) and in the same market size quartile within the industry;
$\ln SALES_{it}$	sales	log of sales (*SALE*);
γ_i and τ_i	pay for luck	γ is the sensitivity of pay to good luck and τ is the sensitivity of pay to bad luck, both from the equation $\ln C_{ij} = \alpha_i + \beta_i R_{ij} + \gamma_i GL_{ij} + \tau_i BL_{ij} + \varepsilon_{ij}$ (Equation (4)) and measured on a firm-by-firm basis over the period a firm used the intrinsic value method for option grants as described fully in the paper. Parameters γ and τ are found separately for each of the five pay components (option grants, stock grants, equity grants, cash compensation, and total compensation);
$GAMMA_i$ TAU_i	pay for luck	$\log(1 + \gamma_i)$ when $\gamma_i \geq 0$, and $-1 * \log(1 + abs(\gamma_i))$ otherwise. *TAU* is found as $1 * \log(1 + \tau_i)$ when $\tau_i \geq 0$, and $-1 * \log(1 + abs(\tau_i))$ otherwise. *GAMMA* increases and *TAU* decreases with increasingly CEO-advantageous pay for luck;
PGL_i PBL_i	pay for luck	*PGL* is an indicator variable equal to 1 when γ_i is greater than sample median, and 0 otherwise; *PBL* is an indicator variable equal to 1 when τ_i is less than the sample median, and 0 otherwise; and
$TREND_{ij}$	calendar trend	$TREND_{ij}$ is equal to fiscal year j minus 1992. *TREND* indexes observations by calendar (fiscal year) time.

BOOK REVIEWS

Stephen A. Zeff, Editor

Editor's note: Two copies of books for review should be sent to the Book Review Editor: Stephen A. Zeff, Rice University, Jesse H. Jones Graduate School of Business, 6100 Main St., Houston, TX 77005. The policy of *The Accounting Review* is to publish only those reviews solicited by the Book Review Editor. Unsolicited reviews will not be accepted.

RONALD J. HUEFNER, *Revenue Management: A Path to Increased Profits* (New York, NY: Business Expert Press, 2011, ISBN 13: 978-1-60649-141-6, pp. x, 145).

In reading Ronald Huefner's book, I could not help but be reminded of my own experiences in teaching cost accounting and management. Teaching materials and plans in this area inevitably revolve heavily around concepts and techniques for allocating costs and measuring the profitability of products, services, and customers, leaving comparatively little time for the "so what?" questions. Once the measurement is done, how should we use the information to improve profitability?

Without a systematic framework, this part of the discussion can quickly become a generic exercise in developing a "laundry list" of broad approaches—such as discount pricing for large and predictable orders, preferential pricing for "strategic" customers, and even the wholesale "firing" of customers—with little in the way of prescription for how to choose among these approaches, let alone facilitate their implementation. These approaches are all variants of differential pricing, and Huefner's book reminds us that the field of revenue management provides the appropriate systematic framework for making these choices optimally. In doing so, the book makes a strong case for the need to better integrate cost and revenue management processes within organizations.

Huefner's target audience is practitioners, and the book seems to be particularly aimed at accounting and financial managers. Perhaps appropriately, given this target audience, the book is written at a relatively high level and focuses on providing a general introduction to revenue management applications and techniques as well as methods for measuring and monitoring their efficacy. The "30,000 foot" view taken in the book, however, presents both strengths and weaknesses. On the one hand, it makes the topic of revenue management in all its various forms accessible at an introductory level. On the other, it allows little in the way of detailed guidance for developing or implementing revenue management practices within organizations.

It is, of course, difficult to accomplish both tasks in one book. Huefner's focus on the former makes the book most appropriate for financial and accounting managers who need a general introduction to the topic of revenue management. It may also be useful for marketing and operations managers who need a general introduction to cost accounting concepts that can be utilized to evaluate and ensure the profitability of revenue management processes.

The first two chapters highlight the importance of revenue management as a field and provide a brief historical overview of its origins in airlines, along with its subsequent development and application in a variety of other service industries. Chapter 2 provides a particularly useful overview of industry- and firm-level characteristics that give rise to the demand for revenue management, including the presence of fixed and perishable capacity (e.g., airline seats, hotel rooms), high fixed costs, and uncertain but predictable demand patterns.

Chapters 3–6 focus on the integration of revenue management with various cost measurement and analysis techniques, ranging from contribution margin and capacity analysis to opportunity costs and the theory of constraints. Huefner provides a strong case in this section for the role of cost systems in ensuring the success of revenue management efforts. In drawing a much-needed link between cost and revenue management techniques, this is perhaps the strongest portion of the book. However, given the target audience of finance and accounting managers who are likely to understand cost accounting concepts comparatively well, these chapters tilt too heavily toward cost measurement rather than revenue management. This is most notable in Chapter 5, where Huefner provides a very good, and relatively detailed, overview of the CAM-I capacity model, but devotes less than a paragraph to applying the model in revenue management decisions.

Despite this, Huefner should certainly be given some credit for drawing the link between capacity cost analysis and revenue management. Detailed models of an organization's cost structure should allow managers to proactively assess, for any given level of revenue-generating activity, the appropriate level of capacity required in various types of resources (personnel, office space, hardware, and other indirect support resources). In this vein, his work in Chapter 5 appropriately articulates a view similar to that of Cooper and Kaplan's (1999) "fundamental equation of activity-based costing," which goes something like the following:

Cost of Resources Supplied = Cost of Resources Used + Cost of Unused Capacity.

The left-hand side of this equation captures the cost of resources committed during a particular accounting period, while the right-hand side simply partitions this cost into the costs of resources utilized in productive and non-productive activities. As Cooper and Kaplan point out, cost systems like activity-based costing are focused on the right-hand side of this equation—modeling the costs of resources used and, by extension, providing transparency into where unused capacity exists in the organization. With information from such cost systems in hand, managers need to decide whether to reduce unused capacity by reducing the cost of resources supplied (cost management) or by reallocating that capacity to productive revenue-generating use (revenue management).

Chapters 7–9 focus on the "bread and butter" issue of revenue management—differential pricing. These chapters provide a broad overview of different approaches to segregated pricing (e.g., by customer, location, distribution channel, or product) and more specific techniques such as discounting, bundling, and markdowns. While these chapters are useful in providing a review of different pricing approaches that fall under the broad umbrella of revenue management, the weakness of the "30,000 foot" approach is apparent here, as no guidance or framework is offered for choosing which approaches work best and under what circumstances.

Chapters 10–12 point to potentially important roles for accounting and finance professionals to play in measuring and monitoring the efficacy of revenue management efforts within organizations. These chapters highlight the importance of considering the effects of current revenue management efforts on future customer behavior and profitability. The price discrimination at the heart of many revenue management techniques carries potential risks for organizations in the form of customer perceptions of unfairness, eroded trust, and reduced loyalty (Chapter 10). Revenue management decisions, in the form of price discounting, bundling, and other techniques also need not necessarily result in more profitable customers (Chapter 11).

Huefner begins to address the issue of how to measure all of these effects in Chapter 12, where he advocates a detailed analysis of different revenue sources. Overall, these chapters do a good job in highlighting the importance of these issues, but the ideas could be pushed further—particularly with regard to what type of management reports and reporting processes would be necessary to monitor, evaluate, and manage the risks and benefits of revenue management efforts over time.

In sum, the book serves as a good introduction to revenue management concepts for finance or accounting professionals who are unfamiliar with this field. More importantly, it provides a call to arms for better integration of revenue and cost management systems and points to an important and relatively unexplored role for these professionals in monitoring, evaluating, and managing ongoing revenue management efforts within organizations.

Reporting Business Risks: Meeting Expectations (London, U.K.: ICAEW Financial Reporting Faculty, 2011, ISBN 978-0-85760-291-6, pp. v, 79). Downloadable at http://www.icaew.com.

Reporting Business Risks: Meeting Expectations is a thought leadership piece developed by the ICAEW's Financial Reporting Faculty as part of its *Information for Better Markets Initiative*. In response to calls for improved disclosures on entity business risks following the global financial crisis of 2007, its stated purpose is to make "a timely contribution to debate about how risk reporting should evolve" (p. iii). The principal authors are Brian Singleton-Green and Robert Hodgkinson.

Chapter 1 discusses the growing demand for risk reporting and highlights a series of past reports issued by the ICAEW, calling for improved risk disclosures, beginning with *Financial Reporting of Risk: Proposals for a Statement of Business Risk*, published in 1997. Chapter 2 discusses implications of selected prior research studies involving quantitative or qualitative risk disclosures and concludes that researchers "often express a degree of disappointment with it [risk reporting], sometimes suggest that disclosure requirements have had a limited effect, and tend to make comments along the lines that there is 'formal disclosure but substantial non-disclosure'" (p. 16). Chapter 3 presents the authors' views on challenges to risk reporting, and in Chapter 4 the authors present seven principles they propose that are potentially generally applicable [across industry sectors] "points for consideration by those interested in improving risk reporting and by preparers of corporate reporting information" (p. 35).

The publication should be a useful primer on business risk reporting for those who have not followed related developments in the U.S. and abroad. For example, Appendices 1 and 2 provide summaries of current risk reporting requirements embodied in U.S. SEC regulations, EU Directives, German law and accounting standards, the U.K. Corporate Governance Code and related guidance, the Basel II Accord and IFRS, as well as excerpts from selected "significant" documents calling for improved risk reporting that have been published during the past 20 years. However, the report falls short of my high (perhaps unattainable) personal standard on what constitutes thought *leadership*.

I do not believe that the "seven principles for better risk reporting" presented in Chapter 4 constitute thought leadership. These principles are: (1) tell users what they need to know, (2) focus on quantitative information, (3) integrate into other disclosures, (4) think beyond the annual reporting cycle, (5) keep lists of principal risks short, (6) highlight current concerns, and (7) report on risk experience. These guiding principles are useful but not particularly revealing.

On the positive side, the discussion presented in Chapter 3, on risk reporting challenges, highlights some significant impediments to effective risk reporting (e.g., the inherent unreliability of forward-looking information and costs versus benefits perceived by managers). For example, the authors recount the following issue raised during a 1997 discussion between researchers and standard setters in the U.S.—"there is no ex post settling up so there is no basis for assessing completeness or accuracy of risk disclosures" (p. 20)—and conclude in the Chapter 3 summary, "It is impossible to know even after the event whether most qualitative, and some quantitative, risk reporting is accurate or inaccurate. This must limit the reliance that users can place on it" (p. 31). On this issue, I believe additional thought-provoking discussion could have been provided by the authors on questions such as what sources of evidence, if disclosed, would help illuminate to investors the nature, extent, and time-horizon of principal business risks and what, fundamentally, it means to "settle up" within a risk assessment and response context. During the period of high inflation in housing prices leading up to the financial crisis of 2007, some financial institutions may have adopted a high-risk, high-return strategy of loosening credit underwriting standards in order to increase the volume of mortgages written and securitized, while other institutions may have adopted a more conservative strategy of tightening such standards to mitigate the risk of future loss should future prices revert toward the mean. Would qualitative disclosures of such strategies, and changes in them over time, have improved investors' understanding of the nature, extent, and time-horizon of risks? Is the execution of such a strategy verifiable? Auditors already review credit underwriting policies and procedures, related internal controls, and samples of other loan documentation when assessing the reasonableness of provisions for loan losses and fair value estimates for retained interests. What are examples of principal business risks for which there is no "ex post settling up?" Additional discussion on questions such as these would have been helpful to me.

Also, Chapter 3 includes an interesting discussion on risk-disclosure costs versus benefits as they might be perceived by managers. The authors differentiate a cost-of-capital reduction due to reducing information asymmetries from a cost-of-capital increase in response to increased transparency of downside risks. The implication is that managers may rationally resist additional downside risk disclosures that may reduce information asymmetry, because the net effect on the firm's cost of capital and managers' remuneration would not be beneficial to the manager. Such would be the case if, for example, the reduction in a security's risk premium due to increased market-wide confidence in the completeness and accuracy of company disclosures is more than offset by the increase in the risk premium caused by revelation of "worse than expected" downside risks. This might help explain why managers prefer "substantial non-disclosure of risks," but I believe that the inclusion of additional discussion that links implications of risk opacity back to investor behavior, moral hazard, and market efficiency would have provided for a more comprehensive discourse on costs versus benefits.

In Chapter 4, I was particularly interested in section 4.5 on thinking beyond the annual reporting cycle, where the authors recommend that "consideration be given to how risk reporting . . . might be taken out of the annual reporting cycle and instead updated as the need arises on firms' websites" (p. 41). I found appealing the notion that such an approach would increase the speed and frequency of feedback on changes in risk assessments and related outcomes, and this made me wonder whether, and if so how, more timely feedback and response could possibly have dampened financial and behavioral trends preceding and continuing into the financial crisis.

Also, I was interested in the Chapter 4 discussion in section 4.2 on the guiding principle, "focus on quantitative information," particularly the authors' proposal that "The stress tests organized by banking and insurance supervisors also provide valuable information about risk, and it would be helpful to explore the use of such disclosures as an additional form of risk reporting by banks and insurers" (p. 37). However, I found somewhat contradictory the authors' conclusion following this proposal that "In general, we do not think that attempts to quantify the probability of one-off future events or to forecast the potential losses that might result from them are likely to provide useful information" (p. 38). This statement appears to me to suggest that the authors believe that disclosures involving scenario or sensitivity analyses likely would not heighten users' awareness of risks.

Consider the following statement made by Robert S. Kaplan during his plenary address to the 2010 Annual Meeting of the American Accounting Association: "[Lehman Brothers] somehow failed after a 5 percent decline in US real estate prices. After 40+ years of academic research on capital markets and financial economics, is Lehman's [2008] 10-K disclosure the best we can offer to quantify and disclose a company's risk exposure? I hope not." (Reproduced in Appendix 4, Risk Reporting and the Financial Crisis, p. 73.) Lehman did disclose the following qualitative risk information in its 2008 annual report: "Further declines in real estate values in the US and continuing credit and liquidity concerns could further reduce our level of mortgage loan originations and increase our mortgage inventory while adversely affecting its value" (p. 73). Now, let's suppose that Lehman had disclosed not only this qualitative information, but also their best estimate of what percentage decline in real estate prices would likely impair their ability to meet current financial obligations. Would such a disclosure have reduced information asymmetry? Should regulations require quantitative disclosures of best estimates of such "tipping points" for the principal risks threatening the reporting entity? Would such estimates be more reliable and verifiable than measures involving management's estimate of the probability that the tipping point (5 percent decline in real estate prices) will obtain? Would such a disclosure prompt investors to make their own assessments of the probability of a 5 percent decline in real estate prices? Additional discussion in section 4.2 on questions such as these may have improved my understanding of the rationale supporting the authors' conclusion that they "do not think that attempts . . . to forecast the potential losses that might result from them [one-off future events] are likely to provide useful information."

Finally, I was somewhat surprised that, against the backdrop of the recent global financial crisis and growing demand for better risk reporting, substantial variance in risk reporting requirements across different jurisdictions, and evidence suggesting current risk reporting requirements often have only limited effectiveness, the authors concluded, "[F]or these reasons, we do not propose new or tougher regulation of risk reporting" (p. 35). I believe in the old saying, "If it's not broke, don't fix it." However, if investors around the world who purchased mortgage-backed securities in the period leading up to the financial crisis were blind-sided due, in part, to a poor understanding and estimation of risks, which was due, in part, to opacity, which was due, in part, to ineffective risk disclosure regulation, a continuing debate on how risk reporting regulations might be improved seems warranted.

In conclusion, perhaps the ICAEW's current report *is* thought leadership, as my reflections on its contents have prompted my consideration of a variety of issues pertaining to the current state of affairs in business risk reporting that, in turn, has *led* my thinking to new places. For me, personally, the work achieved its stated purpose: to make "a timely contribution to debate about how risk reporting should evolve" (p. iii).

Annual Report and Editorial Commentary for *The Accounting Review*

John Harry Evans III
University of Pittsburgh

I. INTRODUCTION

Having completed one year as *The Accounting Review*'s (*TAR*) Senior Editor, I appreciate the opportunity to report to the AAA Publications Committee and Board of Directors, and to the readers, authors, reviewers, and fellow co-editors of *TAR*, as well as to share some of my thoughts on *TAR* processes. I believe that such communication concerning *TAR* and our editorial processes will give all constituents, including prospective authors, a better sense of what we seek to do and how we seek to do it.

II. *THE ACCOUNTING REVIEW* EDITORIAL PROCESS

My experience as one of 13 co-editors during Steve Kachelmeier's 2008–2011 regime has been very helpful to me during my first year in this position. Because I found Steve's editorial approach and specific policies to be effective, I have generally continued them. The biggest change during our first year was the conversion to the AllenTrack online submission and manuscript management system, which I will discuss later in this report. Key policies that we continued include delegating most editorial decisions to co-editors, while centralizing a reviewer-selection process that is critically important, in part because of *TAR*'s two-reviewer system. We also centralize communication with reviewers, editors, and authors as all such communications go through the *TAR* office via the AllenTrack system.

My impression when my term started was that finding the right *TAR* "team" would be the most important determinant of how effectively the *TAR* system would operate in the next three years. Today I believe this even more strongly. Our team is comprised of 14 knowledgeable and fair-minded co-editors, 143 insightful and conscientious Editorial Board members, and 543 *ad hoc* reviewers; an Editorial Assistant, Stacy Hoffman, who is both incredibly fast and almost infallible; and doctoral student research assistants, Michele Frank and Eric Chan, who know, or can learn, who does what very well in almost every conceivable area of accounting research, and even more importantly, which of these experts are available to review a manuscript on any given day. When the rest of the team does their job in a conscientious and skillful manner, there is not much the senior editor can do to mess things up, and of course, the converse is also true.

During the 12 months before my term started on June 1, 2011 my two biggest tasks were recruiting the *TAR* "team" described above and determining whether an online manuscript processing system would work for *TAR*. On the first challenge, each of my fellow co-editors was very gracious and generous when I approached them with an exceptional opportunity; i.e., the

Published Online: November 2012

chance to increase their workload significantly and lose further control over their personal schedule, all while making potentially contentious decisions and receiving no compensation. Other team members have been correspondingly professional, efficient, and generally a pleasure to work with.

Six months before my term started, I feared the worst in terms of the prospective conversion to an online submission and manuscript management system. Fortunately, AAA leadership, particularly Publications Manager Diane Hazard, orchestrated a change in vendors to Allen Press. Our technical support from Elizabeth Garrett at Allen Press has been extremely responsive and effective in working with Stacy and me.

Stacy, Elizabeth, and AAA Publications Assistant Lindsay Peters organized a relatively seamless transition whereby all submissions starting June 1, 2011, whether new manuscripts or revisions, entered the new online system, with Stacy manually entering the data for a number of manuscripts originally processed under the previous email-based system and for authors unfamiliar with such systems. At the same time, we maintained a parallel email-based system to support processing of some of the other 190 manuscripts that were already "in play" as of June 1, 2011. I have compared our two operating manuscript management systems in parallel, each with hundreds of manuscripts, to operating a railroad with both an "old train" and a "new train" running at the same time on roughly parallel tracks, while gradually transferring the "passengers" (manuscripts) to the "new train" whenever possible. After 12 months, I am happy to say that virtually all passengers are now on the "new train" online system with essentially zero lost passengers, delays, or complaints in the process, for which I cannot thank Stacy and Elizabeth enough. Further, my sense is that most authors like the online system, and even if a few would have preferred we not change, they have adapted and have done so without complaining loud enough that I could hear.

Stacy and I meet most days with *TAR* doctoral research assistants, Michele Frank and Eric Chan, to identify reviewers and an editor for recently submitted manuscripts. Michele and Eric alternate days attending the *TAR* meeting, bringing to our meeting their research of the literature in the area of each new manuscript to identify two or three potential reviewers from our Editorial Board, one of whom we will select and Stacy will invite via the online system, and the other(s) whom we will list as the alternate if the first choice declines. Likewise, using the same general approach, we identify a primary and alternate second reviewer, who typically is not an Editorial Board member. The second reviewer may be more or less experienced than the Editorial Board member, depending on the specific circumstances unique to each manuscript. Further, the online system assigns the terms "Reviewer #1" and "Reviewer #2" based on the sequence in which we receive the reviews, so these terms do not reveal any particular characteristics of the reviewers.

We almost always have at least five to ten new manuscripts in need of reviewers, and during periods of heavy submissions, the inventory of new manuscripts ready for an invitation to reviewers and an editor can grow to 25 or so, which we attempt to gradually work down over the next several weeks. Our output becomes Stacy's input as she first seeks agreement from the editor to handle the manuscript and to either accept the proposed pair of reviewers or to suggest alternative names. Once the editor has agreed on two reviewers, Stacy invites the reviewers and if both agree to review, Stacy uses the online system inventory to track the progress of the reviews. As a result, we require an average of two weeks to identify potential reviewers, receive agreement from the proposed editor to handle the manuscript using either the proposed reviewers or alternative names the editor prefers, invite the reviewers, and receive their agreement, along with inviting alternative reviewers when our first choices decline. The final section of this report returns to this issue by examining the distribution of manuscript turnaround times.

III. EDITORIAL AND PUBLICATION STATISTICS

Table 1: Annual Activity Summary

The 2012 report follows the structure of Steve Kachelmeier's 2011 report (Kachelmeier 2011), which should facilitate comparisons across years. As a general overview comment, the 2012 workflow was generally similar to that in 2011. I will next discuss the results shown in each of the tables.

Table 1, Panel A reports *TAR*'s comparative workflow statistics for each of the years 2009–2012, with the data on a journal year basis from June 1 of one year through May 31 of the following year. Panel A shows that in 2012 the volume of new submissions increased to 568 from 495 in 2011, with the 568 figure being very close to the 557 submissions received in Steve's first year, which ended May 31, 2009. Likewise, the 153 resubmissions in 2012 are comparable to the 163 resubmissions received in the first year of Steve's regime, but somewhat below the resubmission totals of 212 and 228 in his second and third years. This probably reflects some authors accelerating their revision efforts in an attempt to achieve closure on a final decision before the change in editorial regime on June 1, 2011.[1] Finally, Panel A of Table 1 shows that overall *TAR* sent out 722 editorial decisions during the year ending May 31, 2012, which is up slightly from 708 decisions in 2011.

Next, to permit comparability to years before 2009, Table 1, Panel B provides data on the calendar-year (CY) basis, which was used in 2008 and previous years. Panel B indicates that the total of 582 new manuscripts submitted to *The Accounting Review* in CY2011 continues a trend of growing submissions. Although the growth rate has slowed in recent years, new submissions today are at approximately twice the level in 2000. The third and fourth columns of Table 1, Panel B show that the increased submissions prompted an increase from four to five issues a year in 2006, and then to six issues a year in 2008, along with an even greater increase in the annual *TAR* total page count from approximately 500–600 pages in 1998–2000 to more than 2,200 pages in 2010 and 2011.

Table 2: Annual Outcome Summary

The four lines of Table 2, Panel A report the outcomes for the total decision letters (column (e)) generated during each of the fiscal years 2009–2012. The final two columns of Panel A of Table 2 use the data in columns (a) to (e) to generate two estimated annual "acceptance rates" for each of the last four fiscal years. For 2012, Rate 1 in column (e) divides the 75 acceptances by the 75 + 426 = 501 "final outcome" decisions, yielding the acceptance rate of 15.0 percent. Rate 2 in column (f) retains the same 75 acceptances in 2012 in the numerator but now adds to the denominator the 221 "Revise and Uncertain Decisions" in 2012, which yields an acceptance rate of 10.4 percent (75/722). Rate 1 can be viewed as an upward biased measure of the acceptance rate, whereas Rate 2 is downward biased, such that the "true" acceptance rate lies somewhere in between—perhaps between 12 and 13 percent for 2012. The results for 2012 in Table 2, Panel A are largely similar to those for 2011, consistent with the current editorial team's decision to generally retain policies from the preceding regime, together with a generally similar experience in the submission and review process in 2012 as in 2010–2011.

Table 2, Panel B presents a second perspective on acceptance rates. Panel B treats each year's set of new submissions as a unique "cohort" and tracks the eventual outcomes for that cohort over the next several years. Thus, the first line of Panel B shows that for the journal year ending May 31,

---

[1] In response to authors' concerns that a revised manuscript received soon after the editorial transition would be handled by a new editor without full appreciation of the manuscript's history, Steve and I have coordinated on a policy that generally seeks to retain the original editor whenever there is more significant doubt about an editorial decision and the original editor is available and willing to continue as editor even though the editor's three-year term has ended. In particular, when a resubmission is received on or after June 1 of the transition year and the reviewers have made split recommendations, we have made every effort to retain the original editor.

TABLE 1

Annual Activity Summary

Panel A: Annual Activity Summary by Journal Year

Journal Year Ending May 31	Manuscripts in Process at Beginning of Year (a)	New Submissions Received (b)	Resubmissions Received (c)	Manuscripts Available For Evaluation (d) = (a) + (b) + (c)	Decision Letters Sent (e)	Manuscripts in Process at End of Year (f) = (d) – (e)
2009	133	557	163	853	719	134
2010	134	502	212	848	673	175
2011	175	495	228	898	708	190
2012	190	568	153	911	722	189

Panel B: New Submissions by Calendar Year

Calendar Year	New Submissions	*TAR* Volume (Number of Issues)	Total Page Count Per Volume
1998	196	Vol. 73 (4)	577
1999	239	Vol. 74 (4)	530
2000	260	Vol. 75 (4)	492
2001	328	Vol. 76 (4)	701
2002	324	Vol. 77 (5)	1,034
2003	327	Vol. 78 (4)	1,108
2004	307	Vol. 79 (4)	1,216
2005	389	Vol. 80 (4)	1,274
2006	413	Vol. 81 (5)	1,181
2007	443	Vol. 82 (5)	1,393
2008	482	Vol. 83 (6)	1,698
2009	508	Vol. 84 (6)	2,094
2010	494	Vol. 85 (6)	2,221
2011	582	Vol. 86 (6)	2,253

Explanations of columns in Panel A:

(a) Manuscripts in process as of the beginning of the year include all new submissions and revisions pending decision (generally awaiting review), but exclude manuscripts awaiting revision from authors.

(b) New manuscripts received during the year, including desk-rejected manuscripts but excluding resubmissions of revised manuscripts.

(c) Resubmissions of invited revisions.

(d) Summation of columns (a), (b), and (c).

(e) Completed decision letters, including subsequent decisions for manuscripts previously evaluated as a "revise and resubmit" decision within the same fiscal year.

(f) Manuscripts awaiting review and/or editorial decision as of the end of the journal's fiscal year. These manuscripts become the "beginning inventory" for the following year.

2009, *TAR* received 557 new submissions (column (a)), of which only one file (column (d)) was still awaiting further revision and a final decision as of three years later on May 31, 2012. Of the other 556, 96 had been accepted (column (b)) and 460 rejected (column (c)), such that the last two columns of Panel B show that the final acceptance rate for this cohort will be 17.2 (17.4) percent if the final study is rejected (accepted).

TABLE 2
Annual Outcome Summary

Panel A: Outcomes by Fiscal Year

Journal Year Ending May 31	Decision Letters Sent (a)	Rejections (b)	Revise and "Uncertain" Decisions (c)	Acceptances and Conditional Acceptances (d)	Acceptance Rate 1: (e) = (d)/[(b) + (d)]	Acceptance Rate 2: (f) = (d)/(a)
2009	719	408	230	81	16.6%	11.3%
2010	673	403	207	63	13.5%	9.4%
2011	708	437	193	78	15.1%	11.0%
2012	722	426	221	75	15.0%	10.4%

Panel B: Final Outcome Resolution for All New Submissions

Journal Year Ending May 31	New Submissions Received (a)	Cumulative Acceptances through May 31, 2012 (b)	Cumulative Rejections through May 31, 2012 (c)	Files Pending Further Revision as of May 31, 2012 (d)	Lower Bound on Acceptance Rate: (e) = (b)/(a)	Upper Bound on Acceptance Rate: (f) = [(b) + (d)]/(a)
2009	557	96	460	1	17.2%	17.4%
2010	502	62	433	7	12.4%	13.7%
2011	496	31	404	61	6.3%	18.6%

Explanations of columns in Panel A:

(a) This column is the same as column (e) of Table 1, Panel A, reflecting all decision letters sent during the fiscal year, including decisions on manuscripts that had been evaluated previously within the same fiscal year (with invitations to revise and resubmit). Thus, the number of unique manuscript files processed is somewhat lower than the number of decision letters sent.

(b) Exhibit 1 separates the total rejections into manuscripts rejected due primarily to insufficient contribution and manuscripts rejected due primarily to a perceived threat to the validity of the reported claims.

(c) Exhibit 1 separates this column into decisions logged as standard "revise-and-resubmit" outcomes and decisions logged as "uncertain" outcomes that allow but do not necessarily encourage resubmission.

(d) Total acceptances and conditional acceptances include manuscripts published and forthcoming in *The Accounting Review*. Thus, the total acceptances during a year do not represent the actual number of articles published during that year. Acceptance totals include only those files accepted from the normal review process, and exclude invited commentaries from AAA Presidential Scholar Lectures and from occasional research forums.

Next, for the journal year ending May 31, 2010, Panel B shows that of 502 new submissions, as of 24–36 months later on May 31, 2012, 62 were accepted, 433 rejected, and 7 remain pending. The last two columns of Panel B indicate that the final acceptance rate for the journal year 2010 cohort will be between 12.4 percent and 13.7 percent, and probably closer to the latter figure because most of the 7 pending files have a good probability of being accepted. Finally, the last row of Table 2, Panel B shows that of 496 new submissions for the journal year ending May 31, 2011 (and as of May 31, 2012), 31 were accepted, 404 rejected, and 61 remain pending, yielding a final acceptance rate between 6.3 percent and 18.6 percent, depending on the how many of the remaining 61 are eventually accepted. Projecting similar results for pending files as experienced last year, the final acceptance rate for journal year 2011 is likely to be 13–14 percent.

The results in Table 2, Panel B suggest that the *TAR* acceptance rate for annual cohorts of new submissions has declined from approximately 17.3 percent in 2009 to approximately 13–14 percent in 2010 and 2011. This pattern, and in particular, the higher acceptance rate in Steve's first year of 2009, is consistent with Steve's projections in his 2011 *TAR* report and reflects a transition effect resulting from the policy decision by the AAA Publications Committee to increase the number of issues and published studies in *TAR*. By generally permitting revision when at least one reviewer was favorable over the first year of their regime, Steve and his co-editors were able to gradually build a buffer inventory of accepted manuscripts sufficient to ensure full issues on a regular basis. As the senior editor following Steve, I am particularly grateful to have taken over with a healthy inventory of approximately nine or ten months of accepted manuscripts, which we have roughly maintained since then. For example, as of June 30, 2012, we have accepted manuscripts to fill the next five issues through March 2013 and are now filling the May 2013 issue.

As a final note on this analysis of *TAR* acceptance rates over the last several years, I wish to emphasize the importance of our general policy of giving individual editors complete discretion on their decisions. In particular, reviewers provide reports and offer recommendations, both of which are absolutely essential, but the final decision is the editor's call. When both reviewers recommend rejection, the editor typically concurs. The more difficult editorial decisions occur when the reviewers are split and/or when one or more reviewers recommend "Uncertain." These are the cases in which the editor truly earns the generous salary that our system provides. My observation is that just as Steve's team of co-editors managed to make appropriate adjustments at the margin to build the inventory in Steve's first year and then became a bit more conservative, our team's editorial judgments appear to be generally consistent with the experience in the latter part of Steve's term. The data so far suggest that this process is generating acceptance rates in line with recent historical experience.

Exhibit 1: Histogram of Editorial Rounds and Outcomes

Exhibit 1 provides further details on the 722 editorial decisions reported in Table 2 for the journal year ending May 31, 2011. Exhibit 1 shows that 534 of the 722 decisions (74 percent) were first-round decisions, while 105 (15 percent) were second-round decisions and the remaining 83 (11 percent) were third round or later. Of the 534 first-round decisions, Panel A of Exhibit 1 shows rejection was the most common outcome, accounting for approximately 72 percent (247 + 137 = 384 of 534) of the first-round decisions, while the remaining 28 percent of first-round decisions were revisions.[2] Panel A also shows that of the 384 first-round rejections, slightly less than two-thirds (247) were due to insufficient contribution and slightly more than one-third (137) were attributed primarily to concerns with the study's validity.

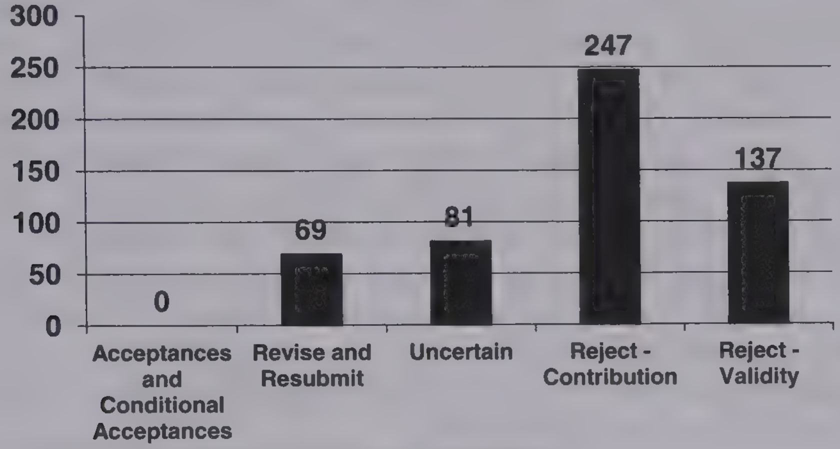
Next, Exhibit 1, Panel A shows that of the 150 decisions in 2012 that permitted the authors to submit a revised manuscript, 69 were standard "revise and resubmit" decisions, while the other 81 were more qualified "uncertain" decisions. Both "revise and resubmit" and "uncertain" have outcome risk, but the degree of that risk is substantially higher for an "uncertain" decision. Specifically, an "uncertain" letter conveys the sense that neither the reviewers nor the editor can envision a viable revision path that would address the identified concerns, but that the editor recognizes that the author might be able to construct such a path. Accordingly, such a letter gives the author an *option* to revise and resubmit, but without explicitly encouraging the author to do so. The intent is to provide full disclosure to the author that withdrawing the manuscript might be in the author's best interest if the author's candid assessment is that the concerns raised cannot feasibly be addressed. Experience indicates that almost all recipients of "uncertain" letters choose to revise and

---

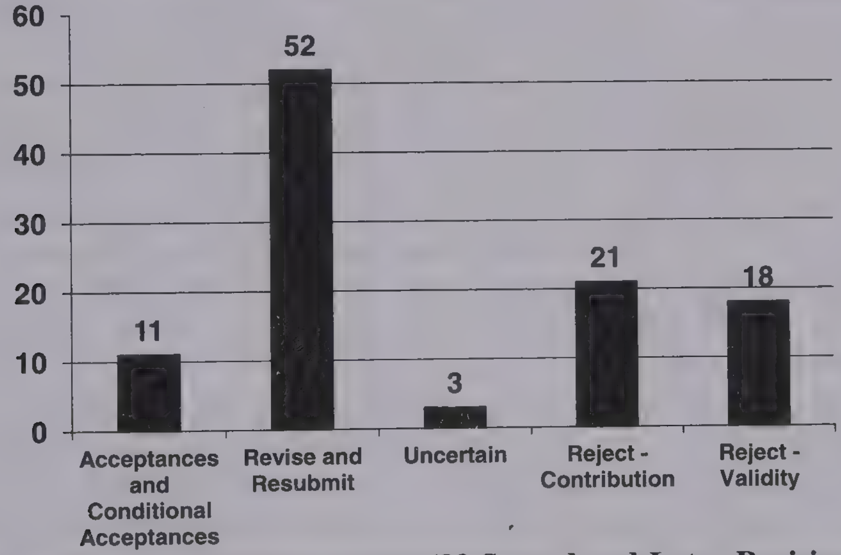
[2] The 384 rejections include 10 desk rejections that were returned to the authors without review and with a refund of the submission fee. I have classified these 10 decisions as rejections due to validity concerns.

EXHIBIT 1
Histogram of Editorial Rounds and 722 Outcomes
Journal Year Ending May 31, 2012

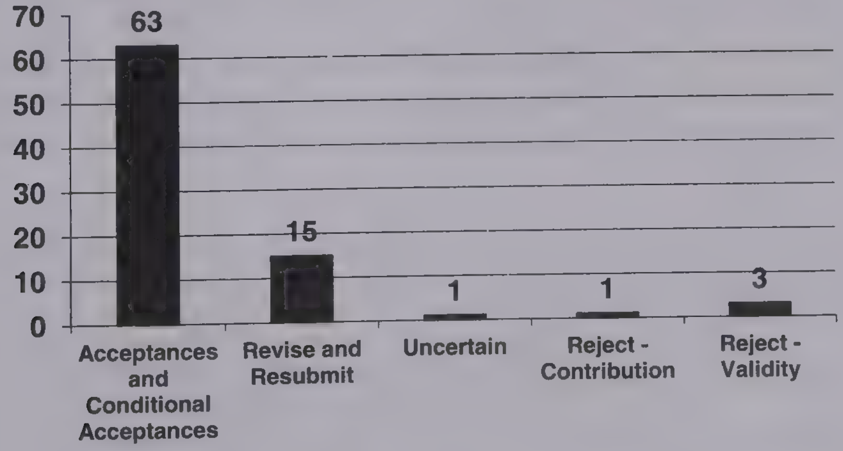
Panel A: First-Round Outcomes (534 New Submissions)



Panel B: Second-Round Outcomes (105 First Revisions)



Panel C: Third- and Later-Round Outcomes (83 Second and Later Revisions)



resubmit in spite of the cautions, but the rejection rate on "uncertain" revisions is substantially higher than that for standard invitations to revise and resubmit.

Moving to the second round or "first revision" decisions, Exhibit 1, Panel B shows that of the 105 total second-round outcomes, 11 were acceptances or conditional acceptances, 55 received invitations for further revision with three of these in the more qualified "uncertain" category, and the remaining 21 + 18 = 39 second-round letters were rejections, which are always painful. Although a second-round rejection is painful, experience suggests that a third-round rejection is even worse. This consideration compels editors to make difficult decisions on manuscripts that appear to have potential but that achieved only limited progress in the first revision.

By the time a manuscript gets to the third round or beyond, Exhibit 1, Panel C documents that the odds of success increase dramatically, with 63 of the 83 fiscal 2012 decisions being acceptance or conditional acceptance, a rate of 76 percent. Sixteen manuscripts received a further revise and resubmit during the third or later round, and four manuscripts were rejected at this advanced stage of the process. Of course, we seek to minimize such late round rejections by making the tough decisions sooner whenever possible, but in some cases further rounds appear to be the most appropriate decision despite the risk, in which case we go ahead. Finally, we note that Panel C also includes eight fourth-round decisions, four fifth-round decisions, and one sixth-round decision; nine of these 13 decisions were conditional acceptances.

Table 3: Submissions and Acceptances by Subject Area and Research Method

Panels A–D in Table 3 describe how submissions compare to acceptances by subject area, by research method, and by the combination of the two. The results offer important insight concerning patterns and trends, including whether submissions in certain subject areas or using certain methods were more or less likely than others to be published in *TAR* over the years 2009–2012. These panels are helpful in responding to conjectures that *TAR* systematically favors or disfavors particular areas or methods of research, where the conjecture may stem simply from comparing the number of publications across topic area or research methods. Table 3 provides careful, systematic data and enables readers to see the importance of evaluating acceptance rates only in light of the corresponding submission rates.

My impression is that this approach has been largely successful in generating a more informed discussion of these issues in recent years, so I am continuing it. Please note that Table 3 counts each study only once even though many studies go through several rounds of revision before eventually being published or rejected. This approach means that the figures in Table 3 will generally not agree precisely with those in Tables 1 and 2, which treat each submitted version of a study as a distinct manuscript, whereas Table 3 counts each study only once even if multiple versions of the manuscript are submitted across several rounds.

The general pattern in Table 3 indicates that *The Accounting Review* accepts articles at rates that generally track the corresponding submission rates very closely, whether by topic, by method, or by topic crossed with method.[3] The overall similarity in submission and acceptance rates is

---

[3] The most noticeable deviation between 2012 submission rates and acceptance rates in the Table 3 occurs in Panel A for the financial accounting area, which accounts for 47.8 percent of all submissions but only 36.7 percent of all acceptances for the year 2012, as shown in the left-hand portion of Panel A. The corresponding results for the most recent four years in the right-hand portion of Panel A show financial accounting comprising 51.3 percent of all submissions and 46.9 percent of all acceptances. Conversely, Panel A reports that the managerial accounting area accounts for 13.0 percent of all submissions but 26.5 percent of all acceptances for the year 2012 and 12.8 percent of all submissions and 18.1 percent of all acceptances for the most recent four years of 2009–2012. In both cases the differences in rates between submissions and acceptances declines when we look over a longer period, consistent with the differences being temporary deviations.

TABLE 3

Submissions and Acceptances by Subject Area and Research Method Journal Year Ending May 31, 2012

Panel A: Submissions and Acceptances by Subject Area

In Panels A and B, subject (Panel A) and method (Panel B) categories are as directed by the AAA Publications Committee. Manuscripts that overlap categories are assigned to the category that best captures the study's primary objective, as judged by the Senior Editor. To avoid double-counting invited revisions, the total of 678 unique submissions in each panel excludes submissions earlier within the year for which multiple decisions were recorded within the year on the same manuscript files.

In Panels C and D, cell entries reflect submissions first, followed by acceptances (in parentheses). The first and second rows for each cell indicate raw counts. The third and fourth rows compute percentages of the 678 unique submissions for fiscal 2012 (Panel C) and the 2,200 unique submissions for the four years from June 1, 2008 to May 31, 2012 (Panel D), excluding earlier submissions of the same manuscript files to avoid double counting for invited revisions.

consistent with the journal's policy of not emphasizing one area or method over another, but rather seeking to reflect the broad interests of AAA members. In turn, this general similarity in submission and acceptance rates is driven by our process of selecting editors and reviewers. By choosing reviewers for each submission who are experts in the area of that submission, we seek to subject each submission to a comparable review process.

Authors obviously exhibit self-selection preferences in determining the journals to which they direct their submissions. Although *TAR* publishes far fewer studies in the accounting information systems area or manuscripts that employ field-study methods than archival financial accounting studies, this difference in publication rates is driven primarily by differences in submission rates rather than by differences in acceptance rates. To see this, compare the two percentages in the lower row of each cell of Table 3, Panel D. The first (second) percentage indicates that cell's percentage of all submissions (acceptances).

In this way Table 3, Panel D allows one to compare the percentage of all submissions and acceptances by area and method over the last four years, 2009–2012. For example, the cell in Table 3, Panel D for the combination of the financial accounting area and the archival research method reports "44 percent (38 percent)," indicating that over the last four years 44 percent of all *TAR* submissions have been financial archival studies, while 38 percent of all acceptances have been financial archival studies. The resulting differential of [Acceptance Rate – Submission Rate], which is –6 percent for this cell, is the least favorable toward acceptance of any cell in Panel D, consistent with financial archival studies being the least-favored category of studies by this measure over 2009–2012.

In contrast to the preceding example, the overall pattern of submission and acceptance rates in Table 3, Panel D shows a generally very close correspondence between the two rates. Other than the –6 percent difference noted above, none of the cells have differences with absolute values greater than 2 percent. The only other distinctive pattern that I see in Table 3, Panel D is that managerial accounting studies have greater acceptance rates than submission rates across all four research method categories, resulting in the bottom row showing that managerial studies for all research methods represent 13 percent of submissions but 18 percent of acceptances. In my view, the rate differentials documented here are worth noting and worth tracking in the future. I believe that they reflect primarily random fluctuations that are not likely to persist over time.

The preceding comparison of submissions and acceptances across areas is related to the general *TAR* policy of openness with respect to a variety of research areas and methods within accounting. One of the important signals that the *TAR* senior editor can send with respect to openness to research in particular areas or using particular methods is through design of the team of *TAR* co-editors. For example, I have continued the prior regime's approach of signaling *TAR*'s openness to research in the accounting systems area and to studies using field-based methods by inviting Vern Richardson and Ken Merchant, respectively, to serve as *TAR* editors, continuing the approach that Steve began by inviting Jim Hunton and Shannon Anderson to support these same objectives. Although Table 3, Panels A and B indicate no acceptances in 2012 in either of these two cells, I can assure you that Ken, Vern, and I are eager to identify and publish outstanding research in these categories.

More broadly, I have found the process of identifying an ideal team of *TAR* editors to be one of the most challenging aspects that a new senior editor faces. The challenge comes from attempting to balance the desire to have an editorial team with subject matter and method expertise across a wide range of areas and methods, while at the same time keeping the total number of editors manageable and balancing the workload equitably across editors. An individual author would ideally prefer an editor with considerable expertise and enthusiasm for the author's research area and method, but this is not likely to be feasible for every manuscript in every area/method combination. Steve and I discussed these associated trade-offs at length as I sought to recruit the best possible team of editors.

Two important decisions that I made in attempting to address this issue should help to provide insight concerning why every area/method combination cannot have an expert among the co-editors and not every manuscript can be handled by an editor with expertise in the subject area. My first decision was to expand the total number of editors (besides the senior editor) from 13 in the prior regime to 14. The goal of this expansion was to improve our coverage of various area/method combinations.

Second, I made a conscious effort to adjust the mix of editors to better match the mix of expected submissions. While there is certainly no *TAR* system of designated "slots" for specific editor "types," it is important that the mix of editor expertise corresponds appropriately to the mix of submitted manuscripts. For example, there are obvious advantages to having an editor with tax expertise to handle tax submissions, and similarly for other areas and methods. With this rationale in mind, relative to Steve's distribution of 13 co-editors, I adjusted the mix of editors slightly away from the experimental/behavioral area and toward the financial archival area. I also used the additional 14th editor position to recruit Mike Ettredge to handle empirical auditing studies, an area that Steve could handle himself, given his auditing expertise, which I lacked.

I based these decisions on data showing that the editors with primary behavioral/experimental expertise handled, on average, significantly fewer manuscripts annually than the target figure of 40–50 new submissions per year that Steve and I advertised when recruiting editors. At the same time, Steve had to request some editors with financial accounting archival expertise to handle more than 50 manuscripts per year. Therefore, I made the shift to balance the workload across editors, while simultaneously attempting to balance the typical editorial expertise that authors would encounter across areas and methods.

To expand on the latter point, the senior editor effectively serves as the "residual claimant" for most manuscripts under the current system, such that when we receive more manuscripts than we have capacity to handle in a particular area over a given period of time, the senior editor generally handles these excess manuscripts. From my experience and what I understand of Steve's experience, such overflows are common, such that the senior editor is often writing decision letters outside his or her primary area of expertise. In my view this is a natural result of variation in the inflow of manuscripts, and reflects circumstances that our system can handle effectively. However, one unavoidable result is that some authors will necessarily receive a decision letter written by an editor without primary expertise in the topic or method of the study. In such cases the senior editor will almost always rely more heavily on the reviewers than he or she might if the manuscript were in his or her primary area of expertise. Of course, this can work either for or against the author's prospects of acceptance, depending on the reviewers' evaluation of the manuscript.

Table 4: Author Affiliations

Employer Affiliations

Table 4, Panel A tallies the employer affiliations of all authors who have published in *The Accounting Review*, with separate columns for Volume 87 (calendar year 2012) and four-year cumulative totals for Volumes 84–87 (calendar years 2009–2012). As in prior Annual Reports, Panel A adjusts for co-authorship by attributing $1/k$ of an article to each of its k coauthors. If an author lists two affiliations, then Panel A allocates half of that author's $1/k$ share to each. However, because Panel A does not adjust for faculty size, universities such as The University of Texas at Austin and University of Illinois at Urbana–Champaign with larger research-active faculties have an obvious advantage in the rankings.

Table 4, Panel A lists institutions in rank order based on the cumulative four-year column, as evidence of the extent of concentration/diversity among *TAR* authors. Both columns exclude invited commentaries from AAA Presidential Scholar Lectures, which we accept by policy, as well as three

TABLE 4 (continued)

Panel C: U.S. and Non-U.S. Submissions and Acceptances

	Journal Year Ending May 31, 2012	
	Number (Percentage) of Submissions Representing Unique Manuscript Files with Decisions	Number (Percentage) of Acceptances
U.S. Institutions	347.65 (68.2%)	36.92 (78.5%)
Non-U.S. Institutions	161.92 (31.8%)	10.08 (21.5%)

Panel D: Geographical Breakdown of Non-US. Submissions and Acceptances, Journal Year Ending May 31, 2012

	Number (Percentage) of Submissions Representing Unique Manuscript Files with Decisions	Number (Percentage) of Acceptances
Canada	22.33 (4.3%)	0.50 (1.1%)
Mexico, Central, and South America	0.00 (0.0%)	0.00 (0.0%)
Europe	49.25 (9.6%)	2.83 (6.0%)
Middle East	4.42 (1.0%)	0.00 (0.0%)
Africa	0.00 (0.0%)	0.00 (0.0%)
Australia and New Zealand	23.25 (4.5%)	1.33 (2.8%)
Asia	62.67 (12.2%)	5.42 (11.5%)
Total Non-U.S.	161.92 (31.8%)	10.08 (21.5%)

Panel A reports author employer affiliations for all articles published in *The Accounting Review* in Volume 87 (calendar 2012) as well as the four-year cumulative totals for Volumes 84–87 (calendar years 2009–2012), excluding invited commentaries. For articles written by k coauthors, the table allocates $1/k$ of an article to each coauthor's affiliation. For authors indicating two affiliations, that author's $1/k$ share is allocated equally to both affiliations.

Panel B reports author Ph.D.-granting affiliations for the same periods and is constructed in the same manner as in Panel A. An asterisk in Panel B signifies a university that Williams and Rodgers (1995) and Williams et al. (2006) identify as one of 15 "elite" schools.

Panel C reports data for international affiliations, allocating $1/k$ of each manuscript to each of k coauthors. Submissions data for the journal year ending May 31, 2012 reflect the 512 unique files for which decisions were reached in fiscal 2012 based on original submissions or resubmissions in fiscal 2012. Manuscripts for which two or more decisions were reached within the year due to invitations to revise and resubmit are counted only once. We do not include the 190 files for which decisions were made in fiscal 2012 based on submissions or resubmissions prior to fiscal 2012. Acceptance data reflect all acceptances and conditional acceptances reached in the journal's fiscal year 2012, including some acceptances that are scheduled for publication in early 2013, but excluding acceptances based on submissions or resubmissions received prior to June 1, 2011. Hence, the 47 acceptances in this panel do not equal the total acceptances in Panels A and B of Table 4, because Panels A and B only reflect actual articles published in the respective calendar years, excluding forthcoming articles accepted for future publication. The 47 acceptances will also differ from the 75 acceptances for 2012 in Panel A of Table 2 because the 75 acceptances include manuscripts from the 190 files for which decisions were made in fiscal 2012 based on submissions or resubmissions prior to 2012.

Panel D shows the geographical breakdown for the fiscal 2012 non-U.S. submissions and acceptances tallied in Panel C.

invited discussions from research forums, two in 2009 and one in 2012. I also note here that the *TAR* conflict-of-interest policy precludes a *TAR* co-editor or senior editor from serving as editor on a colleague's submission.[4]

The 278 articles included in the four-year cumulative column of Table 4, Panel A reflect 187 different affiliations, with the cumulative article count by affiliation ranging from a high of 11.5 articles to a low of 1/6 of an article (a three-coauthored article with two affiliations for one of the coauthors). In terms of relative concentration/diversity of employment, the 187 different affiliations over four years suggest a limited concentration in *TAR* over this period. The ten highest-ranked affiliations tallied in the Table 4, Panel A cumulative column account for 24.0 percent of the 278 total articles, which is slightly less than the 25.3 percent top-ten statistic similarly computed for *The Accounting Review* by Swanson et al. (2007, 1262) in their analysis of concentration in articles published across four accounting journals and across ten nonaccounting business journals from 1990–2002. Swanson et al. (2007, Table 2) report that *TAR* and *Contemporary Accounting Research* are less concentrated than the other two accounting journals they consider, and that *TAR* is seventh in concentration when compared against ten prominent nonaccounting business journals. Overall, these results are consistent with only a moderate level of affiliation concentration in *TAR* in recent years.

Ph.D. Affiliations

Table 4, Panel B tallies the doctoral alma maters of *TAR* authors published in calendar year 2012 and cumulatively from 2009–2012, attributing $1/k$ of each article to each of its k coauthors, and excluding invited AAA Presidential Scholar Lectures and three invited forum discussions. Panel B lists programs in descending order of the cumulative four-year frequency of doctoral affiliations by school. Without endorsing the notion or measurement of "elite" doctoral programs (Williams and Rodgers 1995; Williams et al. 2006), the data in Panel B of Table 4 indicate that these Ph.D.-granting institutions, identified by an asterisk (*), comprise 42 percent of the *TAR* articles published from 2009 to 2012, which is less than the 62 percent figure reported by Williams et al. (2006, 792) for 2005. The 42 percent is also lower than the 52 percent and 47 percent figures that Williams et al. (2006) apparently characterize as being relatively more reasonable "elite" concentrations from the late 1970s and early 1980s. The general conclusion that I take away from Table 4, Panels A and B, is that *TAR* has been relatively diverse in terms of author affiliation and author Ph.D.-granting institution over the years 2009–2012.

International Affiliations

Table 4, Panel C reports data on international affiliations. The trend from fiscal 2011 to fiscal 2012 is toward increasing percentages of submissions and acceptances from outside the U.S. For fiscal 2012, authors employed outside the U.S. account for about 31.8 percent of *TAR*'s submissions versus about 30 percent for fiscal 2011, and for 21.5 percent of acceptances versus about 20 percent for fiscal 2011. One interpretation of the fact that non-U.S. submissions exceed non-U.S. acceptances is that *TAR* responds less favorably to submissions from non-U.S. authors. However, my personal belief is that it more likely reflects the existence of correlated underlying characteristics that are associated with perceptions of manuscript quality.

---

[4] In the same spirit, a manuscript submitted by a *TAR* senior editor should be handled either by one of the other current editors or by another qualified individual such as a previous editor. A manuscript that I coauthored was originally submitted to *TAR* shortly before the May 2011 transition. Steve Kachelmeier agreed to serve as editor with all files and communication routed through Steve rather than through the *TAR* office so that the identity of reviewers, etc., remained blind.

Table 4, Panel D drills deeper by documenting the fiscal 2012 non-U.S. submissions and acceptances by major geographical region. Of the submissions, Canada (4.3 percent of total fiscal 2012 unique submissions), Europe (9.6 percent), and Asia (12.2 percent) constitute the most frequent contributors. Among the acceptances, every non-U.S. region experiences an acceptance percentage somewhat lower than its corresponding submission percentage. While one might ideally like to see the same general equivalence in our distributions of international submissions and acceptances that we experience for different research topics and methods, I nevertheless find it noteworthy—from the "glass half full" perspective—that one in five successful *TAR* authors resides outside the U.S. and that this percentage is increasing.

Table 5: Processing Time

Table 5 reports processing time data for the 722 editorial decisions reached from June 1, 2011 through May 31, 2012, defining "processing time" as the number of days from the submission to the date when Stacy Hoffman sends the decision letter. Our mean and median processing times for 2012 are 96 days and 94 days, up slightly from 90 and 93 days in Steve and Mary's final year. Stacy and I believe that these measures will improve in our second year. In particular, we will focus on reducing the upper tail of 17.1 percent of all manuscripts that require beyond 120 days to process. I expect our greater familiarity with the AllenTrack system to enable us to do so.

IV. NOTES OF THANKS AND RECOGNITION

Now for some thanks and much deserved recognition! Stacy Hoffman, *TAR* Editorial Assistant, has clearly earned the first place in line. The only way an operation like this can succeed (and I will presume we qualify) is with someone who has her or his finger and mind around every single detail at every single minute, and who knows how each and every detail relates to one another. I surely cannot do this, but Stacy can, thank God! When we first posted the announcement for the position on the University human resources system, I almost immediately received a message from Stacy on my faculty email account saying essentially, "Look no further; you have found the person for the job!" When I met Stacy and checked her background, I could see that she was right. Besides being "incredibly fast and almost infallible" as noted earlier, Stacy is always here, always has a smile on her face, interacts very positively with everyone from disgruntled authors and confused reviewers to lost students who wander into our office and the often-bewildered senior editor. Stacy works late and comes in weekends to try to keep up with the flow of manuscripts and, of course, without compensation. Finally, she has extraordinarily good judgment in resolving myriad issues, allowing me to focus on just a few. She is indeed a godsend!

Second, I thank Katz doctoral students Michele Frank and Eric Chan for their excellent performance as *TAR* research assistants. They perform the critical function of identifying potential reviewers with accuracy and thoughtfulness, whether the pile of manuscripts requiring reviewers is small or large. They have also pitched in cheerfully on important tasks such as assembling data for this report. Their dependability, good spirit, and precision are much appreciated. I have every confidence that they both will be highly successful accounting faculty members in a few years.

Third, I enthusiastically thank the 14 outstanding scholars who have joined me in assuming editorial responsibilities for *The Accounting Review* over this first year of our three-year term—Mike Ettredge, Dave Guenther, Leslie Hodder, Amy Hutton, Bin Ke, Lisa Koonce, Charles Lee, Ken Merchant, Greg Miller, Don Moser, Mort Pincus, Vern Richardson, Phil Stocken, and Beverly Walther. Most importantly, they have been a reliable source of advice and counsel as we have evolved policies for handling various issues. In addition, I have leaned on each of them to make a high volume of very important decisions in a timely, consistent, conscientious, and most important, thoughtful and insightful manner. I have also leaned on various editors to handle extra

TABLE 5

Processing Time from Date of Submission to Date of Sending the Decision Journal Year Ending May 31, 2012

Processing Time	Number of Manuscripts	Percentage	Cumulative Number of Manuscripts	Cumulative Percentage
≤ 15 days	6	0.8%	6	0.8%
16–30 days	16	2.2%	22	3.0%
31–45 days	9	1.2%	31	4.3%
46–60 days	42	5.8%	73	10.1%
61–75 days	100	13.8%	173	23.9%
76–90 days	147	20.3%	320	44.3%
91–105 days	160	22.1%	480	66.4%
106–120 days	118	16.3%	598	82.7%
121–135 days	63	8.7%	661	91.4%
136–155 days	29	4.0%	690	95.4%
156–170 days	13	1.8%	703	97.2%
171–219 days	19	2.6%	722	99.9%
Total manuscripts	722			

Mean processing time: 96 days
Median processing time: 94 days

manuscripts, manuscripts that do not quite fit their backgrounds, manuscripts that require very quick processing, cases of appeals of decisions, etc. In particular, with his office just down the hall, I frequently drop in for a "few minutes" of Don Moser's time, and come away with a clearer appreciation of the issues, even if that takes closer to an hour. Invariably, the co-editor I have asked for special assistance has agreed and has handled even the most difficult cases in a very professional manner. My personal thanks to each of you!

Fourth, perhaps the most fundamental ingredient of a top-quality, peer-reviewed journal process is informed, thoughtful, and objective reviews. To all Editorial Board members, and particularly the 51 members who have completed four to seven reviews for *TAR* this year in addition to the many review requests they must be receiving from other journals, I cannot thank you enough. In addition, we obviously could not operate without the additional 498 *ad hoc* reviewers (named in Appendix A) who completed one or more reviews for *TAR* during the fiscal year ending May 31, 2012. There is no way that *The Accounting Review* could maintain a two-reviewer system without the willing assistance of *ad hoc* reviewers and, to quote Steve, they are "*TAR*'s unsung heroes." Thank you.

Fifth (and he deserves higher billing), I cannot thank Steve Kachelmeier enough for the encouragement and tips that he has provided. Even though Steve is just a youngster, he has played a role for Stacy and me that my "Uncle Cy" played as I grew up in our house with six kids. Uncle Cy was my dad's law partner, a brilliant Harvard Law graduate who always had his "ducks in a row," setting high standards for the rest of us. Whenever one of the kids in our house was trying to get by with a project that was not quite right, the call would go out, "Don't let Uncle Cy see that!" Thanks a million, Uncle Cy! In addition, I thank each of Steve's 13 co-editors who have so graciously agreed when I have requested that they continue as editor on files with split decisions for which they handled the first round. Thanks from the authors and from me.

Sixth, I thank the American Accounting Association, particularly the many outstanding professionals on the AAA staff in Sarasota, as well as the generous academic volunteers who serve on the AAA Publications Committee and Board of Directors. The danger of naming names is that one invariably leaves someone out who should be thanked, but with no slight intended to those not named, the AAA staff professionals Stacy and I have dealt with most often include AAA Publications Coordinator Lisa Habblitz, Publications Assistant Lindsay Peters, and Web/Database Projects Director Kathy Casper. AAA Executive Director Tracey Sutherland has been wonderfully supportive on a variety of critical issues this year with her voice of reason, experience, and good judgment being invaluable. Likewise, I have come to appreciate the calm and thoughtful perspective that AAA Publications Committee Chair Christine Botosan has supplied to keep some difficult issues on track.

Seventh, I thank our contacts at Allen Press, especially Elizabeth Garrett and Kristi Bailey in tech support and Managing Editor Jean Baldwin, for their patience and their prompt and helpful answers to our many questions.

Eighth, I thank the University of Pittsburgh and the Katz Graduate School of Business, Dean John Delaney, and Director of Administration Ron Magnuson for their support of *TAR*, providing Stacy and me with the necessary physical and technology support we need. Thanks also to the generosity of my accounting colleagues at Katz for allowing me to have half-time services from Michele and Eric. Likewise, I thank the many current and former Katz faculty and doctoral colleagues who have generously given their time as reviewers.

Ninth, I thank my accounting academic colleagues at universities around the world for this wonderful opportunity and responsibility of serving as *TAR* Senior Editor. While certainly not all of our decisions have been met with enthusiastic agreement, I believe that, in the great majority of cases, authors have respected the decisions and acknowledged the care and effort that has gone into them. I expect that all editors appreciate the occasional note from an author, whether following an acceptance or a rejection, acknowledging the constructive and objective inputs from reviewers and editors, and this first year has been no exception—thanks!

Last and certainly not least, I thank my family for their support. My dear wife, Karen, has covered for me on many fronts for 42 years now, understanding when I routinely disappear to my third-floor study with a pile of manuscripts. More importantly, Karen and our two daughters, Julie and Kate, organize the logistics that allow me the luxury of doing this job while still staying in close touch with our six grandchildren in Pittsburgh. This includes allowing me to share a bowl of cheerios and blueberries with a hungry two-year-old, to pick up the kindergarten and first-grade brothers at school, to share a sidehill swimming pool with excellent two-year-old and seven-year-old sisters and to ride the Pittsburgh bike trails with a nine-year-old philosopher. How lucky I am!

Mozaffar Khan	University of Minnesota
Jeong-Bon Kim	City University of Hong Kong
Kyonghee Kim	University of Missouri–Columbia
Michael Kinney	Texas A&M University
William Kinney, Jr.	The University of Texas at Austin
Marcus Kirk	University of Florida
Kenneth Klassen	University of Waterloo
W. Robert Knechel	University of Florida
Kevin Kobelsky	University of Michigan–Dearborn
Mark Kohlbeck	Florida Atlantic University
Gopal Krishnan	American University
Jagan Krishnan	Temple University
Linda Krull	University of Oregon
Jason Kuang	Georgia Institute of Technology
Susan Kulp	The George Washington University
Krishna Kumar	The George Washington University
Richard Lambert	University of Pennsylvania
Wayne Landsman	The University of North Carolina at Chapel Hill
Mark Lang	The University of North Carolina at Chapel Hill
Stacie Laplante	The University of Georgia
David Larcker	Stanford University
Chad Larson	Washington University
Christian Laux	Vienna University of Economics and Business
Lian-Fen Lee	Boston College
Kenneth Lehn	University of Pittsburgh
Clive Lennox	Nanyang Technological University
Baruch Lev	New York University
Chan Li	University of Pittsburgh
Edward Li	University of Rochester
Feng Li	University of Michigan–Ann Arbor
Laura Yue Li	University of Illinois at Urbana–Champaign
Ningzhong Li	London Business School
Oliver Li	National University of Singapore
Siqi Li	Santa Clara University
Xu Li	Lehigh University
Yue Li	University of Toronto
Pierre Jonghong Liang	Carnegie Mellon University
Scott Liao	University of Toronto
Theresa Libby	University of Waterloo
Steve Lim	Texas Christian University
Haijin Lin	University of Houston
Steve Lin	Florida International University
Bradley Lindsey	North Carolina State University
Robert Lipe	The University of Oklahoma
Petro Lisowsky	University of Illinois at Urbana–Champaign
Jing Liu	Cheung Kong Graduate School of Business
Jun Liu	University of California, San Diego
Gerald Lobo	University of Houston
Kin-Yew Low	Nanyang Technological University
Tong Lu	University of Houston
Yvonne Lu	Lehigh University

APPENDIX A (continued)

LeAnn Luna	The University of Tennessee
Luann Lynch	University of Virginia
John D. Lyon	The University of Melbourne
Michael Maher	University of California, Davis
Laureen Maines	Indiana University–Bloomington
Mario Maletta	Northeastern University
Christopher Malloy	Harvard University
Sattar Mansi	Virginia Polytechnic Institute and State University
Stanimir Markov	The University of Texas at Dallas
Xiumin Martin	Washington University
Francisco de Asis Martinez-Jerez	Harvard University
Adi Masli	The University of Kansas
Ella Mae Matsumura	University of Wisconsin–Madison
Steven Matsunaga	University of Oregon
Elaine Mauldin	University of Missouri–Columbia
William Mayew	Duke University
Cheri Mazza	Sacred Heart University
Mary Lea McAnally	Texas A&M University
Linda McDaniel	University of Kentucky
Susan McMahon	Texas Christian University
Maureen McNichols	Stanford University
Krishnagopal Menon	Boston University
Molly Mercer	DePaul University
Kenneth Merkley	Cornell University
Bill Messier	University of Nevada, Las Vegas
Michael Mikhail	Arizona State University–Tempe
Brian Miller	Indiana University–Bloomington
Fred Mittelstaedt	University of Notre Dame
Mark Mizruchi	University of Michigan
Phyllis Mo	City University of Hong Kong
Frank Moers	Maastricht University
Emad Mohammad	McMaster University
Don Moore	University of California, Berkeley
Kimberly Moreno	Northeastern University
Karl Muller	The Pennsylvania State University
Sandeep Nabar	Oklahoma State University
Nandu Nagarajan	University of Pittsburgh
Dhananjay Nanda	University of Miami
Ramachandran Natarajan	The University of Texas at Dallas
Gordian Ndubizu	Drexel University
Mark Nelson	Cornell University
Andrew Newman	University of Pittsburgh
David Ng	Cornell University
Jeffrey Ng	Massachusetts Institute of Technology
Terence Ng	Nanyang Technological University
Andreas Nicolaou	Bowling Green State University
Valeri Nikolaev	The University of Chicago
Ed O'Donnell	Southern Illinois University Carbondale
Maria Ogneva	Stanford University
Thomas Omer	Texas A&M University
Paul Pacter	International Accounting Standards Board

Xiao-Jun Zhang	University of California, Berkeley
Yinglei Zhang	The Chinese University of Hong Kong
Yuan Zhang	Columbia University
Yue (May) Zhang	Northeastern University
Yijiang Zhao	American University
Chad Zutter	University of Pittsburgh

EDITORIAL POLICY AND STYLE INFORMATION

EDITORIAL POLICY

According to the policies set by the Publications Committee (which were endorsed by the Executive Committee and were published in the *Accounting Education News*, June 1987), *The Accounting Review* "should be viewed as the premier journal for publishing articles reporting the results of accounting research and explaining and illustrating related research methodology. The scope of acceptable articles should embrace any research methodology and any accounting-related subject, as long as the articles meet the standards established for publication in the journal ... No special sections should be necessary. The primary, but not exclusive, audience should be—as it is now—academicians, graduate students, and others interested in accounting research."

The primary criterion for publication in *The Accounting Review* is the significance of the contribution an article makes to the literature. Topical areas of interest to the journal include accounting information systems, auditing and assurance services, financial accounting, management accounting, taxation, and all other areas of accounting, broadly defined. The journal is also open to all rigorous research methods.

The efficiency and effectiveness of the editorial review process is critically dependent upon the actions of both authors submitting papers and the reviewers. Authors accept the responsibility of preparing research papers at a level suitable for evaluation by independent reviewers. Such preparation, therefore, should include subjecting the manuscript to critique by colleagues and others and revising it accordingly prior to submission. The review process is not to be used as a means of obtaining feedback at early stages of developing the research.

Reviewers and editors are responsible for providing constructive and prompt evaluations of submitted research papers based on the significance of their contribution and on the rigor of analysis and presentation.

MANUSCRIPT PREPARATION AND STYLE

The Accounting Review's manuscript preparation guidelines follow *The Chicago Manual of Style* (15th ed.; University of Chicago Press). Another helpful guide to usage and style is *The Elements of Style*, by William Strunk, Jr., and E. B. White (Macmillan). Spelling follows *Webster's Collegiate Dictionary*.

Format

1. All manuscripts should be formatted in 12-point font on 8 1/2 × 11″ paper and should be double-spaced, except for indented quotations.
2. Manuscripts should be as concise as the subject and research method permit, generally not to exceed 7,000 words.
3. Margins should be at least one inch from top, bottom, and sides.
4. To promote anonymous review, authors should not identify themselves directly or indirectly in their papers or in experimental test instruments included with the submission. Single authors should not use the editorial "we".
5. A cover page should show the title of the paper, all authors' names, titles and affiliations, email addresses, and any acknowledgments.
6. The American Accounting Association encourages use of gender-neutral language in its publications.
7. Experimental studies using human subjects should contain a footnote affirming that approval has been granted by the institution where the experiment took place.
8. Headings should be arranged so that major headings are centered, bold, and capitalized. Second-level headings should be flush left, bold, and both uppercase and lowercase. Third-level headings should be flush left, bold, italic, and both uppercase and lowercase. Fourth-level headings should be paragraph indent, bold, and lowercase. Headings and subheadings should not be numbered. For example:

A CENTERED, BOLD, ALL CAPITALIZED, FIRST-LEVEL HEADING

A Flush Left, Bold, Uppercase and Lowercase, Second-Level Heading

A Flush Left, Bold, Italic, Uppercase and Lowercase, Third-Level Heading

A paragraph indent, bold, lowercase, fourth-level heading. Text starts . . .

Pagination: All pages, including tables, appendices and references, should be serially numbered. Major sections should be numbered in Roman numerals. Subsections should not be numbered.
Numbers: Spell out numbers from one to ten, except when used in tables and lists, and when used with mathematical, statistical, scientific, or technical units and quantities, such as distances, weights and measures. For example: three days; 3 kilometers; 30 years. All other numbers are expressed numerically.

Percentages and Decimal Fractions: In nontechnical copy use the word percent in the text; in tables and figures, the symbol % is used.

Hyphens: Use a hyphen to join unit modifiers or to clarify usage. For example: a cross-sectional equation; re-form. See *Webster's* for correct usage.

Keywords: The abstract must be followed by at least three keywords to assist in indexing the paper and identifying qualified reviewers.

Abstract/Introduction

An Abstract of about 100 words (150 maximum) should be presented on a separate page immediately preceeding the text. The Abstract should concisely inform the reader of the manuscript's topic, its methods, and its findings. The Keywords statement should appear immediately below the Abstract. The text of the paper should start with a section labeled "I. Introduction," which provides more details about the paper's purpose, motivation, methodology, and findings. Both the Abstract and the Introduction should be relatively nontechnical, yet clear enough for an informed reader to understand the manuscript's contribution. The manuscript's title, but neither the author's name nor other identification designations, should appear on the Abstract page.

Tables and Figures

The author should note the following general requirements:

1. Each table and figure (graphic) should appear on a separate page and should be placed at the end of the text. Each should bear an Arabic number and a complete title indicating the exact contents of the table or figure. Tables and figures should define each variable. The titles and definitions should be sufficiently detailed to enable the reader to interpret the tables and figures without reference to the text.
2. A reference to each graphic should be made in the text.
3. The author should indicate where each graphic should be inserted in the text.
4. Graphics should be reasonably interpreted without reference to the text.
5. Source lines and notes should be included as necessary.
6. When information is not available, use "NA" capitalized with no slash between.
7. Figures must be prepared in a form suitable for printing.

Equations: Equations should be numbered in parentheses flush with the right-hand margin.

DOCUMENTATION

Citations: Within-text citations are made using an author-year format. Cited works must correspond to the list of works listed in the "References" section. Authors should make an effort to include the relevant page numbers in the within-text citations.

1. In the text, works are cited as follows: author's last name and year, without comma, in parentheses. For example: one author, (Berry 2003); two authors, (Fehr and Schmidt 2003); three or more authors, (Dechow et al. 1998); more than one work cited, (Cole and Yakushiji 1984; Dechow et al. 1995; Levitt 1998); with two works by the same author(s), (Nelson 2003, 2005).
2. Unless confusion would result, do not use "p." or "pp." before page numbers. For example, (Dechow and Dichev 2002, 41–42).
3. When the reference list contains two or more works by the same author (as the only author or first of two or more authors) published in the same year, the suffix a, b, etc., is appended to the date in the

within-text citations and in the "References" section. For example, (Johansson 2004a, 2004b, 2004c; Baiman and Rajan 2002a, 2002b; Dhaliwal et al. 2005a, 2005b).

4. When the author's name is mentioned in the text, it need not be repeated in the citation. For example: "Cohen et al. (2005) provide ..."
5. Citations to institutional works should use acronyms or short titles where practicable. For example: (NCFFR, The Treadway Commission 1987).
6. If the paper refers to statutes, legal treatises, or court cases, citations acceptable in law reviews should be used.

Reference List: Every manuscript must include a "References" section that contains only those works cited within the text. Each entry should contain all information necessary for unambiguous identification of the published work. Use the following formats (which follow *The Chicago Manual of Style*):

1. Arrange citations in alphabetical order according to the surname of the first author or the name of the institution or body responsible for the published work.
2. Use authors' initials instead of proper names.
3. For two or more authors, separate authors with a comma, including a comma before "and" (Dechow, P. M., R. Sloan, and A. Sweeney).
4. Date of publication follows the author's (authors') name(s).
5. Titles of journals or newspapers should not be abbreviated.

Sample entries are as follows:

Baiman, S., and M. Rajan. 2002a. The role of information and opportunism in the choice of buyer-supplier relationships. *Journal of Accounting Research* 40 (2): 247–278.

Baiman, S., and M. Rajan. 2002b. Incentive issues in inter-firm relationships. *Accounting, Organizations and Society* 27 (3): 213–238.

Berry, R. 2003. Testimony before the Senate Committee on Homeland Security and Governmental Affairs Permanent Subcommittee on Investigations. November 18. Available at: http://hsgac.senate.gov/files/111803berry.pdf.

Cohen, D., A. Dey, and T. Lys. 2005. *The Sarbanes Oxley Act of 2002: Implications for Compensation Structure and Risk-Taking Incentives of CEOs*. Working paper, New York University, University of Chicago, and Northwestern University.

Cole, R., and T. Yakushiji, eds. 1984. *The American and Japanese Auto Industries in Transition*. Ann Arbor, MI: University of Michigan.

Dechow, P. M., R. Sloan, and A. Sweeney. 1995. Detecting earnings management. *The Accounting Review* 70 (2): 193–225.

Dechow, P. M., S. P. Kothari, and R. L. Watts. 1998. The relation between earnings and cash flows. *Journal of Accounting and Economics* 25: 133–168.

Dechow, P. M., and I. Dichev. 2002. The quality of accruals and earnings: The role of accrual estimation errors, *The Accounting Review* 77 (Supplement): 35–59.

Dhaliwal, D., Erickson, and O. Li. 2005a. Shareholder income taxes and the relation between earnings and returns. *Contemporary Accounting Research* 22: 587–616.

Dhaliwal, D., L. Krull, O. Li, and W. Moser. 2005b. Dividend taxes and implied cost of equity capital. *Journal of Accounting Research* 43: 675–708.

Easton, P. 2003. Discussion of: The predictive value of expenses excluded from pro forma earnings. *Review of Accounting Studies* 8: 175–183.

Engel, E., R. Hayes, and X. Wang. 2007. The Sarbanes-Oxley Act and firms' going-private decisions. *Journal of Accounting and Economics* (forthcoming).

Fehr, E., and K. Schmidt. 2003. A theory of fairness, competition, and cooperation. In *Advances in Behavioral Economics*, edited by C. Camerer, G. Loewenstein, and M. Rabin, 271–296. New York, NY: Princeton University Press.

Financial Accounting Standards Board (FASB). 2006. *Accounting for Uncertainty in Income Taxes, and Interpretation of FASB Statement No. 109*. FASB Interpretation No. 48. Financial Accounting Series. Norwalk, CT: FASB.

Levitt, A. 1998. The numbers game. Speech delivered at New York University, Center for Law and Business, September 28.

Maggi, G. 1999. The value of commitment with imperfect observability and private information. *RAND Journal of Economics (*Winter) 30: 555–574.

National Commission on Fraudulent Reporting (the Treadway Commission). 1987. *Report of the National Commission on Fraudulent Financial Reporting*. Washington, D.C.: NCFFR.

Nelson, M. W. 2003. Behavioral evidence on the effects of principles- and rules-based standards. *Accounting Horizons* 17 (1): 91–104.

Nelson, M. W. 2005. A review of experimental and archival conflicts-of-interest research in auditing. In *Conflicts of Interest: Challenges and Solutions in Business, Law, Medicine, and Public Policy*, edited by D. A. Moore, D. M. Cain, G. Loewenstein, and M. H. Bazerman. Cambridge, U.K.: Cambridge University Press.

Rigdon, E. E., R. E. Schumacker, and W. Wothke. 1998. A comparative review of interaction and nonlinear modeling. In *Interaction and Nonlinear Effects in Structural Equation Modeling*, edited by R. E. Schumacker, and G. A. Marcoulides, 1–16. Mahwah, NJ: Erlbaum Associates.

Schultz, E., and T. Francis. 2002. Companies profit on workers' deaths through "dead peasants" insurance. *Wall Street Journal* (April 19): 1.

Securities and Exchange Commission (SEC). 2002. *Certification of Disclosure in Companies' Quarterly and Annual Reports*. Release Nos. 33-8124, 34-46427. Washington, D.C.: SEC.

U.S. House of Representatives. 2002. The Sarbanes-Oxley Act of 2002. Public Law 107-204 [H. R. 3763]. Washington, D.C.: Government Printing Office.

Footnotes: Footnotes are not used for documentation. Textual footnotes should be used only for extensions and useful excursions of information that if included in the body of the text might disrupt its continuity. Footnotes should be inserted using the "footnote" or "endnote" feature of the word processing software which will automatically number the footnotes throughout the manuscript with superscript Arabic numerals.

SUBMISSION OF MANUSCRIPTS

Authors should note the following guidelines for submitting manuscripts:

1. Manuscripts currently under consideration by another journal or publisher should not be submitted. The author must state upon submission that the work is not submitted or published elsewhere.
2. For manuscripts reporting on field surveys or experiments: If the additional documentation (e.g., questionnaire, case, interview schedule) is sent as a separate file, then all information that might identify the author(s) must be deleted from the instrument.
3. New manuscripts must be submitted through the Manuscript Submission and Peer Review System, located at http://accr.allentrack.net. The site contains detailed instructions regarding the preparation of files for submission. Revisions of manuscripts originally submitted before June 1, 2011 should be sent via email to the senior editor, John Harry Evans III, at tar@katz.pitt.edu. Please submit separate files for (1) the manuscript's title page with identifying information (not forwarded to reviewers), (2) the manuscript with title page and all other identifying information removed, and (3) any necessary supplemental files, such as experimental instructions and/or response memoranda on invited revisions.
4. A nonrefundable submission fee is required unless explicitly waived by the editor for invited revisions of previous submissions. The submission fee in U.S. funds is $200.00 for members and $400.00 for nonmembers of the AAA payable by credit card (VISA or MasterCard only). The payment form is available online at: https://aaahq.org/AAAforms/journals/tarsubmit.cfm. If you are unable to pay by credit card or have any questions, please contact the AAA Member Services Team at (941) 921-7747 or info@aaahq.org.
5. Revisions must be submitted within 12 months from the decision letter inviting a revision.

COMMENTS

The Accounting Review welcomes submissions of comments on previous *TAR* articles. Comments on articles previously published in *The Accounting Review* will generally be reviewed by two reviewers, usually including an author of the original article (to assist the editor in evaluating whether the submitted comment represents the prior article accurately) and an additional reviewer who is independent of the original article. If a comment is accepted for publication, the original author will generally be invited to reply. All other editorial requirements, as enumerated above, apply to proposed comments.

POLICY ON REPRODUCTION

An objective of *The Accounting Review* is to promote the wide dissemination of the results of systematic scholarly inquiries into the broad field of accounting.

Permission is hereby granted to reproduce any of the contents of the *Review* for use in courses of instruction, as long as the source and American Accounting Association copyright are indicated in any such reproductions.

Written application must be made to the American Accounting Association, 5717 Bessie Drive, Sarasota, FL 34233-2399, for permission to reproduce any of the contents of the *Review* for use in other than courses of instruction—e.g., inclusion in books of readings or in any other publications intended for general distribution. In consideration for the grant of permission by the *Review* in such instances, the applicant must notify the author(s) in writing of the intended use to be made of each reproduction.

Except where otherwise noted in articles, the copyright interest has been transferred to the American Accounting Association. Where the author(s) has (have) not transferred the copyright to the Association, applicants must seek permission to reproduce (for all purposes) directly from the author(s).

POLICY ON DATA AVAILABILITY

The AAA's Executive Committee policy (originally adopted in 1989, and amended in 2009) is that the objective of the Association-wide journals (*The Accounting Review, Accounting Horizons, Issues in Accounting Education*) is to provide the widest possible dissemination of knowledge based on systematic scholarly inquiries into accounting as a field of professional research, and educational activity. To fulfill this objective, authors are encouraged to make their data available for use by others in extending or replicating results reported in their articles.

NOVEMBER 2012 PLACEMENT ADS

The deadline for free position ads to be included in this section of *The Accounting Review* is two months prior to the desired publication in the January, March, May, July, September, or November issues. Position ads, which are free with the purchase of a job posting in the AAA Career Center, should provide all relevant information about the available positions and must include contact information or application instructions for interested candidates. For more information on how to purchase a job posting in the Career Center, or for up-to-date, detailed information about the placement listings in this issue, please go to the AAA website at http://aaahq.org and click on "Career Center," or call our office at 941-921-7747.

THE COLLEGE AT BROCKPORT, SUNY seeks applicants for a position to teach graduate and undergraduate accounting courses beginning Fall 2013. Teach other business courses as needed consistent with academic/professional experience and the emerging needs of the department's programs. Continuing contributions in the area of scholarship, consistent with standards of performance required for continuing appointment (tenure), AACSB, and graduate faculty standards. Academic and career advisement of students (after first semester). Participation in program/curriculum development. Service activities consistent with the needs of the department, college, and profession (after first year). Continuous professional development. Interaction with stakeholders as needed. Integration of contemporary computer applications into course content. Salary: Competitive Ph.D. or D.B.A. in Accounting from an AACSB-accredited institution. ABD candidates must earn their doctoral degree within six months of hire. Scholarly potential in accounting demonstrated by publications or high-quality work in progress and research plans. Ability to teach in a multi-cultural environment. Strong work ethic and commitment to continuous improvement. Preferred Qualifications: CPA, CFE, CMA, or other professional accounting certification. Demonstrable potential for effectively teaching graduate and undergraduate-level accounting courses. Interest in teaching in the area of forensic accounting. Relevant work experience in accounting. Degree in hand by August 2013. Contact Dr. Donald Kent at: dkent@brockport.edu. Open until filled. Apply at: https://www.brockportrecruit.org/applicants/jsp/shared/frameset/Frameset.jsp?time=1347049560923

MIDDLE TENNESSEE STATE UNIVERSITY, Department of Accounting, located in Murfreesboro, TN, invites applications for two tenure-track faculty positions: (1) tax, rank open (position #110020); and (2) cost/managerial (interest in governmental/nonprofit accounting a plus, other areas considered), Assistant/Associate rank (position #116320). Positions begin August 2013. Earned doctorate in accounting expected (ABD considered if close to completion). Applicants for tax position with J.D. degree from accredited law school and a master's degree in tax will be considered. Department offers a B.B.A. in accounting, a Master of Accountancy, and supports the M.B.A. accounting concentration. Department earned AACSB accounting accreditation in 2004, reaffirmed in 2012. Direct questions to: Dr. G. Robert Smith, Jr. at: smitty.smith@mtsu.edu. Reviews of applications begin September 2, 2012 and continue until filled. To apply go to: https://mtsujobs.mtsu.edu. EO/AA Employer. Women and minorities are encouraged to apply.

UNIVERSITY OF OREGON UNIVERSITY, Lundquist College of Business seeks to fill one anticipated tenure-track position for an Assistant or Associate Professor in Accounting effective September 2013. Duties: publishing in top academic journals, teaching undergraduate and graduate accounting courses, and supervising Ph.D. students. Requires the ability to work effectively with students, faculty, and staff from diverse backgrounds. Requirements: Asst. Prof. level: Completed or nearly completed Ph.D. by Summer 2013 plus demonstrated potential for teaching excellence and ability to publish economics-based research in high-quality academic journals. Senior Asst./Assoc. Prof. level: Ph.D. degree, demonstrated superior teaching competence, and record of scholarly accomplishment that includes publication in high-quality academic journals in accounting or related fields. Salary competitive. For full description go to: http://hr.uoregon.edu/jobs/. Application review begins October 1, 2012; continues until position filled. Application: Send letter of interest, *curriculum vitae*, copies of research papers, evidence of teaching performance, and three letters of reference to: ActgOpenSearch@lcbmail.uoregon.edu. The University of Oregon is an AA/EO/ADA institution committed to cultural diversity.

THE UNIVERSITY OF NOTRE DAME, Department of Accountancy invites applications for position openings at all levels: Assistant, Associate, or Full Professor. All research areas will be considered. The appointment is expected to begin July 1, 2013. Applicants for Assistant Professor positions should expect to complete doctoral degree requirements before the start of the contract period. All candidates should have a strong commitment to scholarly research and excellence in teaching. Salary is very competitive, and research support is excellent. Please submit *curriculum vita*, three letters of recommendation, teaching evaluations, and an example of scholarly work electronically to: acctdept@nd.edu. Also, address inquiries to: acctdept@nd.edu. The deadline for applications is December 7, 2012. The University of Notre Dame is an Affirmative Action Employer with a strong commitment to fostering a culturally diverse atmosphere for faculty, staff, and students. Women, minorities, and those attracted to a university with a Catholic identity are especially encouraged to apply. For more information about the University of Notre Dame, the Mendoza College of Business, and the Department of Accountancy please visit the department's website at: http://business.nd.edu/accountancy/.

UNIVERSITY OF CINCINNATI invites applicants for the position of Department Head of Accounting. The Head's primary responsibilities include leadership of faculty, administration of undergraduate and graduate academic programs, and coordination of business community and alumni relations. As the second largest of ten majors within the Lindner College of Business, accounting plays a *vital* role in the college and has seen significant increases in enrollment in recent years. The University of Cincinnati campus was recently named one of the ten most beautiful in the world by *Forbes Magazine*. Located in the urban center, uptown section of Cincinnati, UC's Accounting Department was ranked in the top ten in the nation in 2009 by *BusinessWeek*. UC is a Research I institution. Applicants should have tenure, or a tenurable record, commensurate with a Research I institution. Previous administrative experience, and/or experience as a Department Head is valuable, but not required. Contact Dr. Jeri Ricketts at: jeri.ricketts@uc.edu. Apply at: http://www.jobsatuc.com/applicants/Central?quickFind=81619. More information regarding UC and the accounting program can be accessed via the UC website at: http://www.uc.edu.

SALISBURY UNIVERSITY, Franklin P. Perdue School of Business is accepting applications for the position of Assistant Professor of Accounting. This position is based in Salisbury Maryland. Primary Job Duties: Teaching at the undergraduate and possibly the graduate level. Minimum Qualifications: Ph.D. degree or ABD in Accounting from an AACSB-accredited institution. If ABD, doctoral degree must be completed before date of hire. Please see full position and required documents at: http://www.salisbury.edu/HR/jobs/. Applications submitted by September 9, 2012 will receive first consideration. The position will remain open until filled. Salary is competitive and commensurate with qualifications and experience. Appointment will be contingent upon verification of eligibility to work in the U.S. and is expected to begin August 2013. SU is an EO Employer, strongly committed to recruiting and retaining a diverse faculty, staff, and student body.

BENTLEY UNIVERSITY, Department of Accountancy at Bentley University invites applications to fill a tenure-track position in the Fall 2013. We are seeking an individual in the financial reporting area, but will consider all qualified applicants regardless of area of specialty. All ranks will be considered. A qualified candidate must have a doctoral degree in accounting (or expect completion of that degree by September 1, 2013), and a strong commitment to excellence in scholarly research and teaching. Interested candidates should submit to the chair of the search committee a current *vita* with a letter expressing interest in a faculty position, evidence of excellence in scholarship and teaching, and the names and phone numbers of three professionals with whom the candidate has worked closely. Recruiting will continue through the 2012–2013 academic year until the position is filled. Please direct inquiries and applications to the Chair of the Faculty Search Committee: Mahendra Gujarathi, Department of Accountancy, Bentley University, 175 Forest Street, Waltham, MA 02452-4705; Phone: (781) 891-2410; Fax: (781) 891-2896; Email: acrecruiting@bentley.edu.

CALIFORNIA STATE UNIVERSITY, EAST BAY invites applications for Assistant or Associate Professor position in accounting to begin Fall 2013. The primary responsibilities are to teach undergraduate and/or graduate accounting or auditing courses, conduct academic research in accounting, and provide service to the University. For an expanded position description and online application instructions, please visit the Wake Forest Employment site at https://wakejobs.silkroad.com/.

BRIDGEWATER STATE UNIVERSITY seeks applicants for an Assistant Professor of Accounting position. Job Description: The primary responsibilities are to teach upper- and lower-level courses in Accounting, with the possibility of teaching select Finance courses and graduate courses. The successful candidate will also participate in the continued development of the graduate and undergraduate curriculum. Required Minimum Qualifications: An earned doctorate or matriculation in a regionally accredited doctoral program in Accounting or an earned master's degree in Accounting, Finance, or related field with professional certification as Certified Public Accountant, Certified Management Accountant, Certified Internal Auditor, or Certified Information Systems Auditor. College-level teaching experience. Preferred Qualifications: Industry/government experience in accounting. Evidence of scholarly activity. Applicants should be strongly committed to excellence in teaching and advising, and to working in a multicultural environment that fosters diversity. They should also have an ability to use technology effectively in teaching and learning, the ability to work collaboratively, evidence of scholarly activity, and a commitment to public higher education. Additional Information: Applications including (1) a cover letter, (2) a *curriculum vitae* that includes contact information for three references, (3) summary information on courses taught and student evaluations, and (4) a brief statement that describes research interests and teaching philosophy may be submitted at: http://jobs.bridgew.edu. Will accept applications until job is fulfilled.

YOUNGSTOWN STATE UNIVERSITY, the successful applicant should possess a doctorate from an AACSB-accredited institution; a major in accounting is preferred. Applicants who are in the final stages of the dissertation process will be considered. Other requirements include an enthusiastic commitment to accounting education and teaching excellence; demonstrated ability to do publishable research in relevant peer-reviewed journals; ability to work with the business community to further the goals of the department, college, and university; and evidence of strong communication and interpersonal skills. Professional certification(s) and experience in the accounting field are also preferred. Date Available: August 2013. Other Information Relevant to this Position: The Lariccia School of Accounting and Finance has 400 accounting majors. The Williamson College of Business Administration (WCBA) has 1,700 undergraduate students with 110 M.B.A. students. The WCBA moved into a new $34 million, state-of-the-art facility in August 2010. Closing Date for Applications: Review of applications will begin immediately and will continue until filled. Applicants must submit the following documents, online only: (1) a letter of application, (2) a current *vita* with employment history and dates, (3) transcript(s) documenting academic qualifications for this position, (4) three references (including name, address, phone number, and email address for each), (5) a statement of teaching philosophy and qualifications, and (6) copies of teaching evaluation summaries (if available). Only online applications will be considered. These documents must be submitted at: http://web.ysu.edu/gen/ysu/Employment__Job_Opportunities_m653.html.

WESTERN WASHINGTON UNIVERSITY invites applications for tenure-track Assistant or Associate Professor position in accounting beginning Fall 2013. Systems or auditing specialization preferred but other specialization areas may be considered. The position is subject to funding availability. Doctoral degree in accounting or equivalent by the appointment date, AACSB academic or professional qualification and strong teaching and research record or clearly demonstrated potential are required. Duties include teaching undergraduate and graduate courses, university service, and scholarly publication. WWU is located between Seattle and Vancouver, BC, overlooking Bellingham Bay and the Strait of Georgia. The University has 14,900 students and the college is AACSB-accredited. Applications must include a letter of application (include how qualifications are met), *curriculum vitae*, evidence of teaching effectiveness, transcripts, and names of three references. All application materials must be uploaded through the Electronic Application System for Employment (EASE) at: http://www.wwu.edu/jobs. Application review begins: September 20, 2012. AA/EO.

ST. BONAVENTURE UNIVERSITY, Department of Accounting invites applications for a tenure-track position at the Assistant or Associate Professor level. The successful candidate will teach undergraduate and graduate courses, predominantly in the area of Financial Accounting and/or Audit. Review of applications will begin immediately and continue until the position is filled. The position appointment is expected to begin with the Fall 2013 semester, contingent upon funding. The candidate will also be expected to undertake scholarly research in a collaborative environment that welcomes inter-disciplinary and practice-oriented scholarship, as well as discipline-based and theoretical work. Applicants must meet the following required qualifications: (1) earned doctorate in accounting or related field by the time of appointment; (2) demonstrated excellence in teaching and willingness to work closely with students in curricular and co-curricular activities, including service, professional, and/or research activities; and (3) an established or emerging research program. Accounting certification and prior professional accounting experience are preferred. The School of Business, accredited by the AACSB, will be moving into its new state-of-the-art Swan Business Center home in Fall 2013. Accounting faculty, students, and programs also benefit from the endowed McQuade Center for Accounting Excellence. The Department of Accounting offers two program tracks: a 120-hour B.B.A. in Accounting and a 150-hour B.B.A./M.B.A. program in Accounting registered for CPA Exam qualifications. Our B.B.A./M.B.A. graduates are highly recruited by Big 4 CPA firms and other large employers. Applications may be submitted online at: accountingsearch@sbu.edu. For additional information please contact the department chair: Dr. Susan B. Anders at: sanders@sbu.edu or (716) 375-2063. St. Bonaventure University is the nation's premier Franciscan university. The University, School, and Department have a strong commitment to achieving diversity among faculty and staff, and encourage applications from members of under-represented groups.

UNIVERSITY OF NORTH TEXAS (UNT), Department of Accounting in Denton, Texas (DFW Metroplex) invites applications for a tenure-track faculty position at the Associate/Full Professor rank. The successful candidate will provide leadership for the program in Accounting, including engaging with faculty and mentoring junior faculty and doctoral students. The Department of Accounting at UNT is committed to academic excellence and diversity within their faculty, staff, and student body. The Department of Accounting offers a full range of academic degree programs including Bachelor of Accounting (B.B.A.), professional 150-hour program (B.S./M.S.) in Taxation or Accounting, M.S. in Taxation or Accounting, and an Accounting doctoral program. For information, visit: http://www.cob.unt.edu/acct. Our programs are among the most innovative in the country, our faculty exhibit expertise in a host of accounting disciplines, and the department is separately accredited by AACSB. Review of applicants will begin immediately and continue until the position is closed. Salary is competitive and commensurate with qualifications. Candidate must hold a doctorate in Accounting (or equivalent) with an established high-quality capital markets and/or archival academic publication record and have demonstrated the ability to work with others in developing and conducting high-quality research. CPA, CMA, CIA or equivalent certification is preferred, but not required. The successful candidate will provide leadership for the capital markets/archival research area, including engaging with faculty, mentoring junior faculty. and doctoral students. For additional information, contact: Dr. Govind Iyer, Chair of the Search Committee at: govind.iyer@unt.edu, or Dr. Don W. Finn, Chair of the Department of Accounting at: don.finn@unt.edu. UNT is an AA/ADA/EOE.

THE UNIVERSITY OF TEXAS AT DALLAS (UTD) invites applications for two faculty positions in Accounting, effective September 2013. Appointment at Assistant, Associate, or Full Professor level will be considered. Appointees must have a Ph.D. in accounting or equivalent (or have a ABD status and expect to have the Ph.D. within a year of hire date) and demonstrate the ability to conduct a nationally recognized research program. Review of applications will begin immediately and continue until the position is filled. The Naveen Jindal School of Management at UTD is a research-centered school, ranked 16th (worldwide) in the UTD database that tracks publications in leading business journals (http://som.utdallas.edu/top100Ranking/). Applicants should submit *curriculum vitae* (education, research, teaching, and student evaluations, work experience, and a list of publications and presentations) and at least three letters of reference at: http://go.utdallas.edu/pmn120911. For more information, visit http://som.utdallas.edu/ or contact Gail Thompson at: bgthomp@utdallas.edu. Indication of gender and ethnicity for affirmative action statistical purposes is requested as part of the application. The University of Texas at Dallas is an Equal Opportunity/Affirmative Action Employer. All qualified applicants will receive consideration for employment without regard to race, color, religion, sex, national origin, disability, age, citizenship status, Vietnam era, or special disabled veteran's status, or sexual orientation.

Tulane
University
FREEMAN SCHOOL OF BUSINESS

ACCOUNTING
A. B. FREEMAN SCHOOL OF BUSINESS
TULANE UNIVERSITY

The A. B. Freeman School of Business is seeking applicants for full-time, tenure track faculty positions at all ranks to begin July 1, 2013. Candidates are expected to hold a Ph.D. in accounting or related discipline and candidates for professor should currently hold the rank of full or associate professor. Salary, teaching load and research support are commensurate with other major research institutions.

We will consider candidates with research interests in any accounting area. In terms of teaching, we seek candidates who have strong teaching skills at all student levels, undergraduate and graduate. At the senior level, we seek candidates who have demonstrated excellence in scholarship and program leadership.

The accounting faculty at the Freeman School has expanded recently and is projected to continue to grow. This year we added Jasmijn Bol, Zhenhua Chen, Kris Hoang, and Padmakumar Sivadasan as new ladder track faculty. Additional information about the Freeman School and the faculty in its accounting area may be found at: http://www.freeman.tulane.edu/desktop.php.

Tulane University enrolls approximately 13,000 students and is a privately funded, comprehensive research university located in New Orleans. New Orleans is a vibrant, multi-cultural community celebrated worldwide for its music, art, and food.

Applicants should send a letter, indicating their interest, and an up-to-date curriculum vitae. All materials should be submitted electronically to:

Sharon Moore (businessdean@tulane.edu)
Executive Assistant to the Dean
A. B. Freeman School of Business
Tulane University
7 McAlister Drive
New Orleans, LA 70118
504-865-5407

Applicants are encouraged to submit materials by November 30, 2012. Screening of applications will begin immediately and will continue until the position is filled.

Tulane University is an equal opportunity/affirmative action employer.

Why use ProQuest business resources from your library?

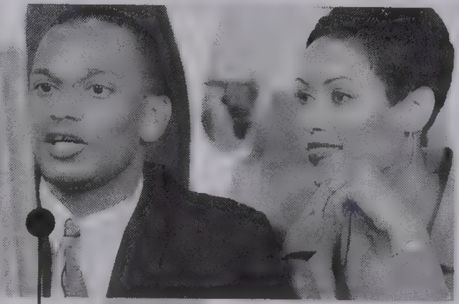
Your library and ProQuest—providing the best business information available

Whether you are a student writing a paper, an instructor recommending classroom support, an entrepreneur contemplating a new venture, or a job seeker researching regional market conditions, you'll be prepared with the resources you need—from ProQuest.

Databases like **ProQuest Accounting & Tax, ABI/INFORM** and **ProQuest Entrepreneurship** feature everything from e-books and annual reports, to education tools and market research reports. And tools like RSS feeds and email alerts keep the search going even when you're not at the computer. All of that is available from your library, via remote access, putting you on the path to discovery, anywhere, anytime.

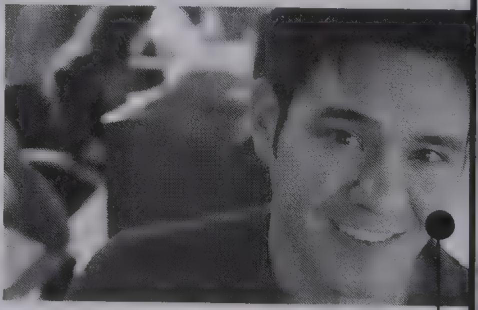
Get free and instant access to hundreds of online databases!

Sure, you can use the open web for research, but when you're looking for authoritative and reliable content, online databases from ProQuest via your local library are your best starting point. Visit your library's website to learn more.



"While I'm in school, I'm also looking for work."

"Even from home, I can log on to get the information I need from renowned databases from ProQuest ... all it takes is a library card!"



"As a small business owner, I'm always seeking resources to help guide my plans."

CHICAGO BOOTH

The University of Chicago Booth School of Business is seeking to appoint outstanding scholars to tenure-track positions in Accounting which would begin in the 2013-14 academic year.

Applications are invited from individuals who have earned a PhD (or equivalent) or expect to receive a doctorate in the near future. Members of our faculty are expected to conduct original research of exceptionally high quality, to teach effectively, and to participate in and contribute to the academic environment. Junior candidates will be judged on potential, and we will rely heavily on the advice of established scholars.

Each candidate should submit a curriculum vitae, a sample of written work, and the names of at least two scholars qualified and willing to evaluate the candidate's ability, training, and potential for research and teaching. Applications will be accepted online at http://facultyapply.chicagobooth.edu. We will start formally reviewing applications on November 30, 2012 and strongly encourage you to complete your application by then. We will continue to accept applications until March 20, 2013.

The University of Chicago is an Affirmative Action/Equal Opportunity Employer.
